Cytotoxicity Testing

The Titertek Supernatant Collection System

Cellular cytotoxicity assays can be performed quickly, economically, and safely with the Titertek Supernatant Collection System. Designed to facilitate the harvesting of supernatant from a standard Titertek/Linbro 96-well, U-shaped microtitration plate, the Titertek Supernatant Collection System separates the cellular components of a culture from the supernatant. Only the isotope released into the supernatant is collected.

- The Titertek Supernatant Collection System is . . .
- Quick** Harvests 96 wells in less than 30 seconds; eliminates centrifugation of plates;
 - Accurate** Collects approximately 90% of supernatant, uniformly absorbs it, avoids traumatization of cells during collection;
 - Convenient** Does not remove cells during supernatant collection; Eliminates cross-contamination between wells; Prevents buildup of isotopes in equipment
 - Economical** Collects most of the supernatant, permitting the use of fewer target cells and less radioactive label.

LKB 2103 Power Supply.

Electrofocusing and constant power are made for each other.

Electrofocusing brings you more information, one-step separation of multi-protein mixtures, and superior resolution. To get all that, you need the high voltage and constant power of LKB 2103 Power Supply. You can use constant power up to 110 W, constant voltage to 2000 V, or constant current to 200 mA. Set by highly accurate vernier dials with locking levers, and read from separate meters.

You avoid hot spots and overheating by presetting a limiting voltage.

You use constant power under continuous automatic control, so that you speed up the process and get better separations.

LKB offers the complete system for electrofocusing: Multiphor, LKB 2103 Power Supply, Ampholine® and Ampholine® PAGplates — your standards in electrofocusing. All supported by LKB Application Notes and *Acta Ampholinae* Literature Reference List.

For more information write to LKB: the only complete source of experience, knowledge and equipment for electrofocusing.

REPRINTS

High-quality reprints of any paper published in **Nature** can be bought in bulk quantity (50 or more).

This service is not restricted to authors.

Typically, 100 2-page reprints would cost £18.90 (£23.50 by airmail); 1,000 would cost £41.35 (£89.70 by airmail). Covers can also be supplied.

Why not write to us for a quotation?

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely.

Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976).

Pakistan needs indigenous medicine

CHINA'S bare-foot doctor, little-educated, trained in his art for only six months, is a constant goad to Pakistan's health-care officials. Why can't Pakistan have similar people? For the conventional doctor with his Bachelor's degree (a five-year, full-time course in medical sciences) is highly expensive and scarce. And even if available, he is not mentally prepared to leave the attractions of the city for the rural areas. So he is ill-equipped to use his medical knowledge.

About three-quarters of Pakistan's people live in the remote countryside, and successive governments have committed themselves to provide a semblance of scientific rural health cover. But there is a largely untapped option in Pakistan, similar to the barefoot doctors of China: the indigenous medicine practitioners. Called the 'hakim', if they practise Greco-Arabic medicine ('Unani Tibb' locally), and 'ved' if they practise 'Ayurvedic', the ancient Indian system, they flourish in the countryside. Could they not be the raw material for a Pakistani bare-foot medical service?

Health care in Pakistan, as in almost the whole of South Asia, is a complex mixture of elements quite different from those in the west. For instance, there are in all about 12,000 conventional doctors in the country for a population of 70 million—hardly one doctor for every 6,000 persons. In practice these provide for only one-fifth of the population. Such a low ratio (for comparison, one doctor to 641 persons in the US, with 45 categories of health personnel to assist him) creates a health care vacuum that fills itself through hakims, veds, homoeopaths and even simple charlatans.

Some 5,000 qualified hakims with diplomas from Unani Tibb colleges already contribute to rural health care; but there are also another 40,000 unqualified hakims who have no formal education nor any medical training. These hakims have learnt just by sitting beside an experienced practitioner in his clinic. Nevertheless, they are recognised and registered practitioners of medicine in Pakistan.

As far as the norms of modern medical science are concerned, even the qualified hakims coming out of the institutions after a 4-year course have a motley education. Along with Greco-Arabic system—which largely works on empirical basis—the hakims are taught several subjects of modern medicine. So the 'kulyat-e-qanoon' of Avicenna is in the curriculum alongside books on modern physiology, anatomy and so on.

Dr Mazhar H. Shah, a Fellow of the Pakistan Academy of Sciences, writes in his recently-published book *the Unity and Integration of Medicine*, that "the teaching of modern subjects [to the hakims] is by people not really qualified to teach; and there are no facilities for laboratory diagnosis and hospital treatment. The result is that Tibb colleges

produce hakims who wear the stethoscope and prescribe both indigenous as well as imported drugs without any knowledge of basic science or pharmacology. This sort of teaching and practice is neither safe for the seriously ill, nor useful to the national health system".

The cost of modern medicine to provide health care to the entire population of the country, on the other hand, appears simply prohibitive and beyond the reach of a developing country. The medical bill for health services alone in Western countries far outweighs the total of the national budget of Pakistan.

So there is a growing realisation that some sort of integration is imperative between expensive modern medicine and the inexpensive indigenous system, which is largely based on cheap local herbs. Thus the hakim and the ved could be taught the essential principles of the indigenous system but also be adequately equipped with basic principles of modern medical science; and not in half-baked fashion as at present, but in a real professional way. A village doctor emerging from such a scheme could use his discretion to use either the local herb or, if available, the relevant Western drug.

The envisaged integrated system, however, may not find smooth sailing in Pakistan due to the many vested interests. The hakim and the ved is generally opposed to integration, as at present he tries to equate himself in social status with the fully qualified western doctor. So does the homoeopath (homoeopathy is a recognised system of medicine in the country). Strangely enough, a good cross-section of western doctors is also opposed to integration as they think that it would down-grade them if systems based on empirical principles are made to dovetail with scientific methods.

Political expediency under pressure from the practitioners of indigenous systems led the Government to set up Autonomous Boards for Tibb and Homoeopathy in 1965 so as to let them "train and practise their systems independently by supplementing such modern advances as the Board may, from time to time determine." However, the government also set up (in 1974) an Indigenous Medicines Commission with Dr Salimuzzaman Siddiqui, the chemist, as its chairman to investigate the possibility of integration of the three systems. The Commission's report was never made public, but it is well-known that it had recommended integration to produce a health service structure on the lines detailed above. But a seal maybe put on the issue by the next civilian government-out of political expediency and to gain political advantage from the strong lobby of tens of thousands 'hakims'. But then that might be the end of integration and also of a practical, down-to-earth answer to rural health care in Pakistan. □

Carter juggles with fast breeder and natural gas

John Douglas discusses how President Carter has managed to enrage combatants on all sides of the fast breeder issue

PRESIDENT Carter has further entangled himself in the meshes of his energy bill — this time through an unlikely deal linking the price of natural gas with research on the fast breeder reactor.

Carter's proposals for price controls on natural gas had been bottled up in a Congressional conference committee for six months, and to free the gas bill for consideration by the full Senate, he needed one more Republican signature on the conference report. So he invited Senator James A. McClure of Idaho to the White House to discuss a compromise. Both parties deny actually making a 'deal', but McClure signed the conference report and an-

Schlesinger also committed the Administration to building the Safety Research Experiment Facility (SAREF), the Fuels and Materials Evaluation Facility (FUMEF) and the High Performance Fuel Laboratory (HPFL) — all of which the President had earlier opposed as part of his policy to shift from "early commercialisation to long-range technical development" of the breeder.

Finally came the matter of the Clinch River Breeder Reactor (CRBR), the costly and controversial demonstration project Carter has opposed since early in his election campaign. Schlesinger wrote that the project would be "discontinued" — without

own party on the issue to ignore the Republican votes Baker can influence. But more important, the compromise suggested to Baker that even if a large breeder reactor were finally authorised, the chances of building it at Clinch River, Tennessee, had been diminished.

Faced with a tough election campaign for his own Senate seat this fall, Baker reacted angrily to what he saw as a personal slight and a threat to a billion-dollar project in his home state. He announced that unless the status of the Clinch River project were cleared up he would no longer support the natural gas bill, which faces strong opposition from a small but determined group of Senators. Without his apparently vital support to cut off debate, under the rules of the Senate a minority of members might well be able to kill the bill by filibustering.

The issue of natural gas deregulation is by far the most complex and controversial section of the National Energy Act finally released by House and Senate conferees. The other three sections — dealing with energy conservation, conversion of power plants from oil to coal, and reform of utility rates — will probably pass easily, but none is likely to have the international impact of the natural gas bill, whose purpose is to lower American oil imports by substituting domestically produced gas.

The conference committee report is the latest salvo in a 39-year confrontation between producers and consumers over government control of gas prices. If enacted, the new law would eliminate the distinction between gas sold within a state and that sold between states. The two categories are now controlled differently. The bill provides that newly discovered gas in both categories would be allowed to escalate in price somewhat more rapidly than inflation until 1985, when all price controls would be removed.

The argument in favour of this loosening of control is that creation of a single gas market will make more gas available to interstate buyers, encouraging them to substitute gas for imported oil. At the same time, this argument goes, rising prices will encourage producers to step up exploration for more new gas. The Department of Energy estimates that by 1985, the equivalent of one million barrels per day of imported oil will have been replaced by domestic gas, representing a 10 percent reduction in total imports, at a \$5 billion annual savings.

Opponents of the gas bill argue that higher prices will only fuel inflation and that recent history indicates that

White House meeting: President Carter, Senator McClure, Energy Secretary Schlesinger.

nounced that he had received assurances from the White House that increased funds for a large breeder reactor no longer faced a Presidential veto. Presumably, some of these reactor funds would find their way to the Idaho National Engineering Laboratory, which has long experience in the breeder field.

Details of the understanding reached on the breeder issue were confirmed in a letter from Energy Secretary James Schlesinger, who also attended the White House meeting. The Administration, he said, would no longer oppose development of a conceptual design for an "improved demonstration project" of the plutonium breeder reactor, although the size was not specified. To fund the entire breeder program \$513 million would be appropriated for fiscal year 1979, \$504 million for FY 1980, and \$520 million for FY 1981. (The Administration had originally wanted to cut back such funding to about \$400 million for the next fiscal year, but the House had already defeated that proposal.)

specifying whether that meant "cancelled" (the earlier wording of Administration policy) or merely "deferred." Some components of the CRBR would be completed and tested, and some of the preliminary licensing would be conducted. A final decision on whether to build this or another large breeder reactor would then be made by 1982.

At first the compromise looked as if it might work. The Administration had overcome a major hurdle facing an important piece of legislation by giving in on a point on which it had already suffered a partial defeat. But in the process of hammering out this compromise, the President and his advisers committed the sort of political blunder that has too often marked the Administration's dealings with Congress: they ignored the Senate Republican leader Howard H. Baker Jr of Tennessee.

Under any circumstances, Senator Baker's cooperation would have been important to the ultimate passage of the natural gas bill, for the President faces too much opposition within his

gas companies will not rush out to drill more wells just because prices are rising. A Chase Manhattan Bank study of the question concluded that "the legislation could actually result in some weakening of the dollar as foreign exchange markets come to perceive that the long-run supply of natural gas in the U.S. is as likely to be reduced as increased." And at least two senators have announced plans to oppose the bill because of their opposition to breeder reactors, now linked to it.

The Carter-McClure compromise is also likely to broaden the debate over conduct of the entire breeder reactor programme. Work is still not complete on the Fast Flux Test Facility (FFTF) a non-power-generating breeder reactor

meant to be a forerunner of Clinch River. First authorised in 1967, FFTF was originally estimated to cost only \$87.5 million but has already passed the billion dollar mark. The CRBR has also experienced severe delays and cost overruns, and both industry and Congressional sources tell *Nature* that any further delay would probably result in a re-evaluation of the basic American breeder design.

During the debate over whether breeder reactors should be built at all, many technologists have reportedly swallowed their specific objections to the CRBR design in hopes of not exacerbating the issue. Specifically, they favour a reactor in which the radioactive molten sodium that passes through the core never leaves the re-

actor vessel and one in which steam for generating electricity is handled at a lower temperature and pressure than now called for. If the Clinch River project is deferred or cancelled in favour of producing a later—and probably larger—reactor, such arguments will probably become much more audible.

It is hard to recall a time when the US energy picture has appeared more cloudy. After he had calmed his initial anger, about the best Senator Baker could say for the recent compromise was "the water has been muddied". All that remains certain is that both the natural gas regulation and breeder reactor issues will take on new dimensions when Congress returns from its present Labour Day recess. □

Boycott of Soviet contacts is for individuals, says NAS

RECENT 'human rights' trials of scientists in the Soviet Union resulted in the immediate cancellation of several major visits by US scientists to the Soviet Union—and these in turn have provoked a biting reaction from the Soviet media—a sure sign that the threat of a severance of scientific relations was a real one. "Future historians will be amazed" wrote the *Literaturnaya Gazeta*, that such reprisals could be contemplated as a means of making the USSR give up "the principles which are sacred to it."

This reaction would appear to substantiate the case for boycott, a case most ably put by Valentin Turchin (*Nature* 273, 256–257; 1978). Not all scientists would support this view, feeling that continuation of contacts makes it possible to express one's concern with the fate of, say, Orlov and Shcharanskii, at least on the personal level, to Soviet colleagues encountered at international conferences.

Thus last month, when the International Congress of Mathematicians was held in the "human rights" city of Helsinki, right on the Soviets' doorstep (subsidised excursions to Leningrad were laid on as a side attraction), several Soviet mathematicians failed to arrive to deliver their papers. One of these people, a Dr Margulis, was scheduled to receive a medal. The ceremony was carried out in his absence, and the formal "presentation" of his work was greeted by a standing ovation, pinpointing in a telling manner the persistent Soviet practice of denying visas to scientists invited to international conferences.

Many would see the stricter insistence on the norms of scientific life—including proper representation at con-

ferences, a more fitting form of protest than an all-out or selective boycott.

Respecting the diversity of views on boycott, the US National Academy of Sciences recently put out a statement calling on world scientists to urge the release of Orlov, Shcharanskii and Sergei Kovalev, a biologist now halfway through a sentence of seven years in a labour camp. The Human Rights Committee of the Academy said:

"These scientists, along with fourteen others in other parts of the world, are of particular concern to this committee, for they represent numbers of colleagues who believe that freedom of intellectual inquiry cannot be divided into two parts—one for the natural world in which we live and one for the society which nurtures us—and who have been imprisoned for acting in accordance with their beliefs".

Nevertheless, the Academy stressed that it does not, as a body, endorse boycotts. "Each American scientist", it concludes, "contemplating a visit to the USSR (or asked to host a Soviet scientist in the US) must determine his or her own course of action."

Interestingly, this decision follows an opposite course to that advocated by a group of French physicists last July, who advocated the severance of all official scientific relations—including conferences—while maintaining personal contacts with Soviet colleagues, making the latter the "occasion of expressing our indignation".

The NAS acceptance of individual choice of protest also underlies the concluding paragraph of a moving appeal which recently reached the West from Kovalev's son, Ivan. Addressing the intending participants of the Fourteenth International Congress of

Genetics in Moscow, he outlined the history of his father's case, and gave a vivid and horrifying picture of prison conditions, he asked for the participants' support, that they would express their attitude towards the imprisonment of their colleague "by means appropriate to you". The appeal has since been circulated by campaigners for boycott, but it is noteworthy that neither Amnesty International, who distributed the letter, nor Ivan Kovalev himself, specifically ask for this.

Nevertheless, the idea of at least a selective boycott does seem to be taking hold in the USA. According to the NAS, its supporters "include scientists who pioneered in the earliest Soviet/US exchanges, seeking to build bridges of common scientific endeavour across the chasm of the cold war. They also include others who have seen themselves as steadfast in resisting the politicisation of science. People have reached their decisions in varied ways: sadness, rather than anger has been the most common emotion".

It is because the response of US scientists is so "individualistic", concludes the Academy, that continued Soviet-US scientific relations are in peril. "Scientific exchange programmes" it says "can be negotiated and organised, but individual participation cannot be commanded. There has been no institutional instruction or decision making, no rush to judgment, and no stampede to boycott. Rather there is a tide of spontaneous response running deep, and it will not be easily reversed in the absence of some judicious and humanitarian actions by Soviet authorities".

Vera Rich

Soyuz is not a trolley-bus, but Comecon flights continue

SIGMUND Jähn, the first East German cosmonaut, together with his Soviet flight-partner Valerii Bykovskii, returned to Earth last Sunday, after a week aboard the Salyut-6 orbiting station. Jähn, the third non-Soviet cosmonaut to visit Salyut, completes the first phase of "international" flights; further launches, with the participation of cosmonauts now in training from other Comecon countries are scheduled for next year.

The manned "Interkosmos" programme, in which the Soviet Union puts into orbit crew members from her Comecon allies did not at first meet with the approval of the entire Soviet scientific establishment. Academician Anatolii Aleksandrov, President of the Soviet Academy of Sciences, was reported to be against any such non-Soviet participation ("Soyuz is not a trolley-bus!"). The programme appears to have been inaugurated partly as a visible expression of fraternal solidarity, and, more practically, as a recompense for the contributions made to the Soviet space programme by the Comecon allies. (It is notable that the first three countries to be honoured by a flight were Czechoslovakia, Poland, and East Germany, whose contribution has been particularly great).

As regards Jähn's particular contribution to the joint mission, one experiment, at least, codenamed "Rech" makes use of his linguistic background. During all communication sessions, he had to repeat "Zwei hundert sechs und zwanzig", so that the parameters of his speech—tone, volume, rate, etc., could be monitored and related to his physical and psychological reaction to weightlessness. (The significance of the number 226 is not clear—nor why the experiment could not have been performed using a Russian repeating "Dvesti dvadtsat' shest'!")

Reaction to weightlessness was the underlying theme of most of the East German experiments, including tissue culture and bacteria metabolism experiments, and an investigation of the cross-linking of micro-organisms and organic polymers. This last used "a Soviet apparatus modified by GDR specialists" (essentially a complex of polythene bags).

And, as in previous "international" flights, the "Splay" furnace was used to produce semiconductor compounds—in this case lead-tellurium and bismuth-antimony compounds, the experimental capsule being renamed for the occasion "Berolina". **Vera Rich**

Taj Mahal out of danger?

THE Indian Government is considering a report from a committee of experts, headed by the chairman of the Indian Petrochemicals Corporation, Dr S. Varadarajan, on how pollution from an oil refinery being built near Agra will affect the Taj Mahal. The committee began its investigations four years ago after fears in scientific circles and in the press that sulphur dioxide waste from the refinery at Mathura 146 km south of New Delhi, would damage the white marble of the Taj Mahal and red sandstone of other historical monuments at Agra, 40 km farther southeast.

The committee's studies revealed that the sulphur dioxide content of the air in Agra is already 15 to 20 micrograms/m³ because of two power plants, numerous small industries and a railway shunting yard there. The refinery, according to the report, would only add a further 1 to 2 micrograms/m³ in the long term, although short-term peak concentrations of 65 micrograms/m³ might be expected under the worst meteorological conditions in winter.

Meanwhile the Government also engaged an Italian firm, Techneco, which specialised in the damaging effects of pollution on marble, to study the problem. The firm in its report ruled out any potential threat to the Taj from the refinery. Another study by the Indian Meteorological Department (IMD) on the expected ground level concentrations of sulphur dioxide in the Agra region because of the refinery also sought to allay the apprehensions. None of the two reports have been made public so far.

However, some experts and technical agencies have expressed doubts about the validity of the findings of Techneco and IMD which they say are based on wind data not of Agra but of Delhi. They alleged that the mathematical models, which were developed abroad, and the constants used were not appropriate for the local weather conditions. The Archaeological Survey of India, which is responsible for the maintenance and conservation of the monuments, is of the view that the emissions from the refinery would certainly discolour and wear away the white marble of the Taj.

Further critics say the Varadarajan committee has avoided the main issue: the report does not say in unequivocal terms whether the threat does or does not exist. They point out that the terms of reference did not include the possibility of shifting the refinery to another site away from Agra. (The Minister of Petroleum and Chemicals, Mr H. N. Bahuguna, had reportedly given the assurance last year that he would reconsider the moving of the refinery to Etawah, 100 km east of Agra, if the expert committee definitely said there was potential danger to the Taj.)

Nevertheless the committee recommends some control measures: that long-term emission of sulphur dioxide from the refinery should be limited to 1 to 2 micrograms/m³ and that three monitoring stations should be set up between the refinery and Agra to keep a constant check on this. The committee also puts forward plans to reduce the overall sulphur dioxide

content in Agra by closing the power plants, switching from coal-fired locomotives to diesel in the shunting yard, moving out some of the present industries and banning from the area any new ones which might add to pollution. It also wants to set up a body to monitor the air at Agra and advise industries on how to keep within acceptable pollution limits.

The Indian Oil Corporation, which has commissioned the refinery, has also taken steps to minimise pollution. Low sulphur fuel oil and gases will be used in the furnaces, and a plant will be installed for the removal and recovery of sulphur. The height of the emission stacks will be increased from 40 metres to 80 metres to ensure better dispersal, and fixed and mobile stations will monitor the concentration of sulphur

dioxide at ground level at various distances from the refinery. These measures will, according to the corporation, limit sulphur dioxide emission from the 6 million tonne refinery to 1 tonne per hour. Installing a planned flue gas desulphurisation unit could reduce this to 0.4 tonne per hour, the Corporation believes.

Corrective action is envisaged if the emissions rise above the safety level. But, critics ask, who will give directions to the refinery each time the monitoring stations give warning that the pollution has risen above the danger level? Moreover, they point out, the recommendations are not mandatory. What is the guarantee that the measures suggested by the expert committee would be fully implemented? And even if all the safeguards are taken, a certain amount of

residual pollution will cause damage to the monuments over a long period.

The latest among the public figures to come out openly against the refinery is the noted ornithologist Dr Salim Ali. In a public statement he called for the shifting of the refinery as "there is a controversy among experts about its effects on the Taj". Dr Ali also spoke about the threat to the famous Bharatpur bird sanctuary near Agra because of refinery gases.

While the Government is yet to take a decision on the Varadarajan Committee report, more than 80 million rupees is reported to have already been spent on the refinery project. There is growing apprehension among critics that it may soon be too late to turn back. □

India plans to invest in tethered balloon technology

WITH the successful ascent of a 270-cubic metre tethered balloon at the Space Applications Centre (SAC), Ahmedabad, on 19 May this year, India has joined the select band of countries like the United States, Britain and France which have developed tethered balloon technology.

According to the Electronics Commission's Information, Planning and Analysis Group, India has all the expertise and indigenous materials to develop this technology on a large scale. A panel on tethered balloon technology, set up by the commission to work out the best plan given available resources and the work in progress in the country, has recommended developing balloons of all sizes—small, medium and big. The panel has also stressed the need for making possible users aware of the potential of balloons.

Research in this technology began in India when tethered balloons were seen as a substitute for the ATS-6 satellite for the continuation of the SITE programme. On the initiative of the Electronics Commission, research was taken up at SAC in April 1974. Apart from the many government and private institutes that helped in designing and testing the balloons, collaboration was sought with the Tata Institute of Fundamental Research, where work was already in progress on plastic balloons.

Two years ago, Tata launched a similar balloon to the present one from its National Balloon Facility at Hyderabad. The present balloon is of medium size, has a payload of 50 kg and can float to an altitude of 1.5 km. Except for two fireproof motors in its pressure regulation system, its components are all Indian made. It carried telemetry and telecommand equipment and batteries.

There is no doubt that tethered balloons are the poor nations' substitute for satellites. Once their technology is developed, they can be used for TV and FM broadcasting, remote sensing, ecology, oceanography, meteorology, coastline management and pollution monitoring. Because they are tethered, height can easily be varied for the study of atmospheric phenomena close to earth. A study carried out by IPAG suggests using balloons in offshore oil exploration as a temporary communication link with offshore platforms.

For communication and TV relays over hilly areas, where building earth-

bound installations is difficult and expensive, tethered balloons can also be used. The panel has said that two balloons at an altitude of 30,000 metres, one at Shillong and another at Dibrugarh, could be easily and cheaply used for a service covering most of the north-eastern hills of India.

The panel also advocates the immediate development of low technology tethered balloons—of low payload and short flight duration. For instance, a tethered balloon with a 10 kg payload, parking at an altitude of 1 km for 24 hours, could be useful to the Meteorological Department and the Institute of Oceanography. Such balloons could also be of use in the MONEX programme scheduled for the 1979 monsoon in the country. The panel has also asked for a study of hazards to the balloons, such as lightning and ultraviolet rays.

Once the technology is fully developed, it is recommended that a national agency should take over to tailor the balloons to the needs of users. How cost effective a tethered balloon can be will be apparent from one example. For a TV broadcast operation for one per cent coverage of India, the total capital investment is 40 million rupees with an annual recurring cost 4.2 million rupees. The same costs for a tethered balloon would be 6.5 million and 1.7 million rupees.

Correction

In 'India prepares to launch Earth resources satellite' (10 August, page 526) it was incorrectly stated that the SEO satellite will be launched from the SHAR range in India. The satellite will be launched in the Soviet Union.

India on stand-by for a plague of locusts

INDIA is standing by for a locust invasion on its borders with Pakistan. Five wireless-linked locust control centres have been established in the border states, and chemicals, men and machines rushed in as locust activity increases. An agreement has been signed between the two countries for a joint strategy to combat the menace. Field officers on either side of the border are meeting regularly to exchange information on locust swarms, egg-laying and emergence of hoppers.

If the locust threat materialises, it will be the second invasion this year. It was in mid-June that the first swarmlets of locusts invaded India. A rare change in wind pattern over the Arabian Sea brought them to Banaskantha and adjoining districts of Gujarat from their original breeding grounds in Africa. The Plant Protection Organisation of the Agriculture

Ministry swung into action and neighbouring states alerted. Benzene hexachloride dust, dusting machines and handpump sprayers were rushed in.

Swarmlets swept in across the India-Pakistan border, and spread to Rajasthan, Haryana and Punjab. They came in small and thin waves. A swarmlet was hardly larger than 3 sq km in area—though a swarm as large as 27 sq km was also spotted in Rajasthan.

India's last locust plague, 16 years ago, destroyed half a billion rupees of standing crop. Except for spoiling leaves and some standing cotton crop in Haryana, the recent invasion did almost no damage—thanks to timely action by the Agricultural Departments of Punjab and Haryana.

Control rooms were set up and anti-locust squads formed. Villagers were trained to report any sign of locust activity. Areas where the locust swarms

had laid eggs were ploughed or sprayed with chemicals. The conventional methods of flame-throwing and digging trenches were also used in some villages, and eventually, all the swarmlets were either killed or paralysed, except one which managed to fly back to Pakistan across the Sutlej river.

The current locust concentration is in the largely desert Saurashtra-Kutch region of Gujarat. At this time of the year, heavy rains turn it into a marshland and a breeding and egg-laying ground for the locusts. Locust swarms have also laid eggs in a large number of villages in Rajasthan.

A total of 100 vehicles, five planes, two helicopters, 100 power dusters and 5,000 hand dusters have already been rushed to these border areas. Border Security forces and the Air Force are also on hand if needed.

Vietnam still looking for foreign aid

VIETNAM'S appeal for more development aid seems to be having a mixed reception. Many countries and international agencies have signed technical and scientific aid agreements with the Vietnamese, but some now have reservations about starting new programmes. The United States refuses to consider any commitment to Vietnam until diplomatic relations are restored.

International organisations provide a substantial proportion of Vietnam's current aid revenue, and a number have commitments within the country. The World Food Programme, for example, has provided US \$89 million since April 1975 for emergency assistance, irrigation work, resettlement programmes in the 'new economic zones' and afforestation programmes. The United Nations Children's Fund is giving \$73 million from 1976–1979 to provide basic health care and primary education and to improve drinking water supplies. In addition the U.N. Family Planning Association (UNFPA) is already operating family planning programmes and will manufacture contraceptives; and the World Health Organisation (WHO) is, to take one example of its activities, training health care personnel.

Financial institutions such as the World Bank and the Asian Development Bank are also to make funds available for projects to improve irrigation, rehabilitate light industry, explore oil resources, and develop telecommunications.

UNESCO and the International Atomic Energy Association (IAEA)

are two of the more scientifically-orientated agencies with an interest in Vietnam. UNESCO is helping to equip the Nha Trang Centre of Oceanography and to set up the Scientific Information and Documentation Centre. (Because of its concern in the field of the restoration of historical monuments, it is also being asked for assistance in restoring the former imperial capital of Hue.) The IAEA feels it could help with the application of isotope and radiation techniques to agriculture and ground water surveys—both given top priority in the country's development programme.

Vietnam is no longer at the top of the UN list of those in need of development assistance—that position is now taken by Angola and Mozambique. But interest in Vietnam has not waned. The report back in March of the Special Commission on Assistance to Vietnam was very well attended. The Soviet Union, China, and the nations of Eastern Europe have long supplied aid to Vietnam and more recently Sweden, Norway and Holland have also established commitments in the country. They are maintaining a keen interest in the redevelopment of the country and are involved in several specific projects.

Vietnam has given science and technology high priority, but most aid agreements favour technology. Those concerned more with science, and involving Western nations, are limited to India, France, West Germany, Canada, Switzerland and the Philippines. These agreements are mainly to provide

advanced training for Vietnamese students.

Lack of technical equipment presents great problems for scientists in Vietnam. This means that research targets are not always met and—for biologists in particular—research programmes are sometimes postponed. The United Nations mission to Vietnam highlighted the needs of Vietnam's scientists, and the UN officials involved with the mission do not hide their disappointment at the apparent disinterest shown by countries supplying scientific aid. They admit, however, that they are not privy to the terms of every bilateral aid agreement and that some countries may be assisting by supplying scientists with vital equipment.

Britain, however, has no immediate plans to supply scientific aid. It is concerned with human rights in Vietnam. The Ministry of Overseas Development (ODM) and the Foreign and Commonwealth Office say that aid already committed to Vietnam will not be affected, but that no new agreements will be made until the government is reassured that human rights are not being violated.

But Britain is not alone. Sweden and Holland have expressed similar concern. They are worried about press reports of refugees leaving Vietnam; of the measures taken to restrict private enterprise in the south of the country; and of the means used to persuade people to move into the new economic zones. The British Government has also shown its concern about human rights in other countries and has

IN Britain today only about 400,000 people work full time on the land. Of these 160,000 are hired workers, 200,000 are farmers (tenants, land-owners and managers) and the rest are members of the farmers' families. Thus Britain, with a total population of 56 millions, has a smaller proportion of its citizens engaged in agriculture than has any other country, be it industrialised or what is now called, optimistically or euphemistically, "developing".

Yet notwithstanding this tiny labour force, food production in Britain is greater than ever before. Were we content with the diet enjoyed by all but the greediest and most prosperous individuals a hundred years ago, we should already be more than self supporting in all foods except things like tea and coffee which do not flourish in our temperate climate. We could survive a seige better than in the last war, when we had a smaller population to feed and nearly three times as many people working on our farms.

Farmers are, however, worried, because the small number of workers means that the industry has little political power. There is probably no single parliamentary constituency in even the most rural part of Britain where the votes of farmers, farm workers and their families would substantially affect the chances of election or rejection of a Member of Parliament.

Thus my own constituency of Huntingdonshire is perhaps the one which is most dependent on agriculture. At the last election the sitting member, Sir David Renton (Conservative) had a majority of nearly ten thousand votes. In this area there are 1,391 farmers, smallholders and market gardeners, and about the same number of employed farm workers. A few of these are below voting age, quite a number are single, and the total strength of the voting force is probably under five thousand. We do not know exactly how these

Farming lobby

KENNETH MELLANBY

people voted in the past, or how they will vote in the future. Large scale farmers are mostly traditionally Conservative, the workers trade union is to the left of the Labour Party, many smallholders are Liberal in their sympathies, so the farming vote is likely to be split. But even if 100% turned out for one candidate, the total would be less than half the present member's majority.

It is partly because their political power is so reduced that British farmers are making greater efforts to develop public interest and sympathy towards their problems. Many thousands of the general public attended the recent Royal Agricultural Show, where various entertainments were provided as well as displays of traditional farming activities. Up and down the country smaller county and district shows set out to cater for the non-farming public, giving them an enjoyable day out and a painless education at the same time. The town dweller at least learns that milk does not originate in bottles and tins, and that their daily bread comes from an arable crop which has its own pest and disease problems.

A recent development has been the organisation of "farm trails". On a Sunday afternoon in late June I went

along to a large arable farm in the fens near to my home. A conducted tour started off every hour. I joined about 150 miscellaneous men, women and children, from town and country. We mounted trailers to be drawn by enormous tractors around the fifteen hundred acre farm. The arrangements went smoothly, though the farm roads were bumpy, and one tractor (a.s., the only British made model) broke down and its load had to crowd onto the four other trailers. We covered several miles on this totally arable farm. We saw fields of wheat, sugar beet, potatoes and green beans. At strategic points we stopped to be addressed by our guide, who explained what each crop was, and the main problems it presented. We were told why they kept no farm animals. We saw immense modern machines, for instance one to harvest beans (for freezing) which cost over £50,000 and was only used for about ten days in each year.

The crops, though not yet ready for harvest, were superb. It was obvious that yields would be greatly above the national average. Those who criticise large farms for being unproductive, in yield per acre, should have been there. Hardly a weed remained in the crops, though odd corners of fields were left uncultivated or planted with native trees and shrubs to encourage wildlife. Even a few hedges remained. This may be the "agribusiness" which many of my conservationist friends so criticise, but we could see how good farmers maintain and improve the fertility of their soil, and even care for the countryside and for the conservation of wildlife. In the depression in the nineteen thirties this farm was derelict, no one was prepared to work it even at the lowest rent. It is now producing enough food to feed all the population of a small town, and its yields continue to grow year after year. The demonstration was evidently an excellent exercise in public relations.

curtailed aid programmes to Uganda and Bolivia.

On the grounds of development alone, Vietnam is regarded by the US as well as Britain as being entitled to substantial aid. But there is little chance of the US supplying official aid in the near future. 1978 is an election year, and officials say that aid for Vietnam is too controversial an issue at present.

Vietnam and the US have not established diplomatic relations; both governments insist on certain preconditions before normal relations can be

restored. Senate officials have been assured, however, that unofficial links between scientists and institutions will not be opposed. Some US scientists are not convinced of the interest of Vietnamese scientists in such exchanges; offers of funding for study in the US have not aroused much response, and several scientists who visited Vietnam in the hope of studying the effects of herbicide spraying found the Vietnamese unhelpful. Such an attitude, however, is not without its political overtones (see *Nature* 271, 597; 1978). For this reason, some

scientists consider that it would be rash to prejudge the Vietnamese on their sensitivity over this issue.

US and UK attitudes to aid to Vietnam are unlikely to have disastrous consequences for Vietnam's current development programme. There could be problems, however, if more countries adopt similar policies. In this case Vietnam's scientists, desperately struggling to overcome the ravages of war on their research programmes would be some of the first to suffer. It is political decisions which will determine the outcome. **Alastair Hay**

Nitrates and nitrites cannot be eliminated

SIR,—The report that nitrite has induced cancer in animals is not surprising as it has long been known to be mutagenic. The benefits from the use of nitrite as a food additive may outweigh the hazards that it presents as a mutagen and carcinogen. The amounts of nitrite in food either 'naturally' or as additives should obviously be kept to the minimum effective levels. Small amounts of nitrites and nitrates are formed by the electric discharge of lighting and it is difficult to avoid this contaminating drinking water.

Nitrate is, however, formed by the decomposition of organic matter and indeed the nitrate used for gunpowder was made in this way until the deposits of Chilean saltpetre became available in the nineteenth century. In conditions of poor sanitation the nitrate formed by "decomposition of organic matter" including faecal residues will be a pollutant. In dry regions this is likely to be present in air as a fine powder and in moist areas as a water contaminant. Improvement in hygiene could therefore remove or reduce a carcinogenic hazard. Nitrite is, however, formed in the intestine by bacterial action (Tannenbaum, S. R., Fett, D., Young, V. R., Land, P. D. & Bruce, W. R. *Science* **200**, 1487; 1978) and it is difficult to see how this could be prevented.

Nitrates are converted to nitrites in the body. Nitrites could be carcinogenic directly by reacting with the purine residues of nucleic acid. They can also act by reaction with secondary or tertiary amines to form nitrosamines which may be metabolised by tissue enzyme to alkylating agents.

The new findings increase the correlation between mutagenicity and carcinogenicity and indicate that exposure to nitrates and nitrites should be reduced although they cannot be completely removed.

Yours faithfully,

E. BOYLAND

Foxing fungus

SIR,—The interesting letter from Maynell and Newsam (3 August, page 466), confirming the suggestion that foxed paper has suffered from fungal attack, raises the question "Why was this form of deterioration called *foxing*?" The dictionary explanation is that the word refers to the brownish colour. If that were all, rusting would have been a more suitable word. I have often wondered whether it is merely a coincidence that several harmful effects, now known to be caused by fungal growth, are verbally related to the fox. For example: fox-evil, now called alopecia from the Greek for a fox; wine fermented by a contaminated yeast culture; and beer that has 'gone off'. Robert Graves argued somewhere

that fox in the Bible is often a mistranslation of *mushroom*. For example: "Take us the foxes, the little foxes, that spoil the vines" (*Song of Solomon* 2 15). He explained the extraordinary story (*Judges* 15 4,5) of Samson tying firebrands to the tails of pairs of foxes, and sending them off to burn the Philistine's crops, thus: "he inflamed his soldiers by feeding them on mushrooms (? *Amanita muscaria*) and sent them in pairs to destroy the crops".

I wonder whether there could have been a similar confusion in other languages. The metaphorical use of fox to describe colour or cunning is understandable. The uses of the word that are discussed here predate recognition of the fungal category. Nevertheless, they all have some connection with observable growth. We get fox from a Teuton rather than a Latin root. Could there have been a confusion between the German *wuchs* and *fuchs*. In English, the f becomes a v in vixen. It would be interesting to know whether any scholarly person has thought about the matter. It's not my subject.

Compulsory boycott

SIR,—Unlike many other people, I never intended to boycott the Fourteenth International Congress of Genetics of Moscow, August 1978. I was very anxious to meet our Russian colleagues. Five communications from members of my department were accepted by the conference organising committee. Two of their authors had even been invited to act as co-chairman for some of the congress sessions.

But the Soviet authorities refused to grant me an entry visa, without giving any motive. To show their solidarity, my collaborators decided to cancel their participation in the congress.

In answer to my protestations made by telegram, I received (on 18 and 19 August) two calls from the organising committee, assuring me that there had been a technical mistake which would be rectified promptly. I was asked to wait for further information. I was still waiting, when the congress was almost at an end.

Who has boycotted the congress? Not I! But will my Russian friends hear of it?

Yours faithfully,

ANTOINE ELENS

Namur, Belgium

Making mincemeat of our common language

SIR,—An American visiting Britain, and wishing to cook a hamburger (whatever its load of carcinogens) is in for a "gastronomic surprise if he acts on the information given by my friend Tom Jukes

(27 July, page 307). If, in an attempt to purchase ground beef he asks for mincemeat, he will receive "a mixture of currants, raisins, sugar, suet etc." (see the Oxford Dictionary), the stuff we British use at Christmas to make the traditional mince pies. If he is lucky, there may even be some brandy in the mincemeat; a hundred years ago our more virile ancestors included steak, but fruit and sweet substances always predominated.

The English synonym for ground beef is simply mince. The shopkeeper would understand what was needed if asked for minced beef.

Marsh mallow grows in Britain

SIR,—Rosemary Angel, in her review (4 May page 79) of *Major Medicinal Plants: Botany, Culture, and Uses*, takes the author, Julia F. Morton, to task for saying that marsh mallow is grown in gardens in Great Britain. "No, I am afraid it is not," she says. Without wishing to be picayune, I feel I should say that it is. I have grown marsh mallow in two successive gardens, and it is one of the most beautiful plants I know. It is growing in my garden now. And I am well aware of the difference between common mallow, musk mallow, marsh mallow, and the others.

Yours faithfully,

ROBERT K. G. TEMPLE

Sex and cancer

SIR,—In his review of A. C. Braun's book, *The Story of Cancer: On its Nature, Causes and Control*, Richard Peto says, "... many, and perhaps most, cancers are caused by certain sexual habits, smoking habits, and gross aspects of diet rather than by contaminants."

For God's sake, Peto, which habits? Are thousands, perhaps millions of human beings to perish through your reticence (or bashfulness)?

And if—as can hardly be doubted—the Regius Professor is correct, can he tell us which sexual habits of plants cause their cancers? Or which smoking habits?

Yours in fear and trembling,

RALPH CHERNOFF

Thin films: present and future

from Robert M. Hill

TWENTY-FIVE years ago, as part of an undergraduate course, I was introduced to the world of thin films. In an evacuated bell-jar a sample of aluminium wire was heated up by a tungsten filament, the aluminium melted then vaporised and condensed on the cold surfaces of the bell-jar and on a microscope slide mounted in a holder. I think the rest of the experiment was to measure the optical transmittance and reflectance of the semi-transparent metal film. The feature that caught my imagination was the extreme thinness of the metallic deposit, somewhat less than 30 atom layers. For the first time atomic dimensions were realisable, structures could be seen to grow and one could visualise the packing of atom layer on atom layer and investigate the physical effects of size down to angstrom dimensions.

The same period of 25 years has seen an amazing growth in the technology of thin films. New methods of deposition, or rather more correctly, improved techniques based on the development of old ideas have become available, a new range of instruments for investigating the structure and properties of films have been developed and there have been major steps in our understanding of the delicate processes of nucleation and growth, and of the effects of structure on the physical properties of films. A major step in the recognition of thin film science was the establishment, in 1966, of a journal, *Thin Solid Films*, specifically devoted to the publication of scientific papers on thin films and their properties. The journal has now brought out its 50th volume (gone are the days when volumes and years kept pace together) and has taken the opportunity of asking the editorial board and contributors to present their personal views of the past and of the future. Scientists, as we all know, are notoriously reticent

about forecasting the long term future, unless one manages to be party to a group relaxing together after a long day listening to interminable papers at a conference or summer school, and there is little crystal ball gazing in this anniversary issue but there is an excellent set of individual views of the past, and particularly the present, state of the field.

The methods of preparation of thin films are many. In this volume alone are descriptions of deposition by vacuum evaporation, chemical vapour deposition, ion beam methods, gaseous adsorption, photodeposition, plasma polymerisation, epitaxial overgrowths and the stacking of monomolecular layers. In principle it seems that any material, element, alloy or compound, can be grown in the form of a thin film. Indeed many alloys can be deposited in metastable forms that are not known in the bulk. The most perfect layers are those grown by epitaxy on single crystal substrates, a technique widely used in the preparation of electronic devices where the interface between film and substrate, or between two different films, of good crystal structure has to be sharp and well defined. Compound formation can be aided by vapour deposition in which chemical reactions are allowed to take place either in the vapour phase or at the growing interface. Much of the recent work on the electrical properties of amorphous semiconductors was carried out on thin film specimens in which the normal crystallisation processes were inhibited by holding the substrate at such a low temperature that the initial surface mobility of the vapour atoms was inhibited and hence the required non-crystalline form obtained.

The wide range of uses of thin films is also clearly shown. The electronics industry is an obvious candidate in these days of planar technology but the dielectric properties of oxides and the low temperature coefficient of electrical resistance of both alloys and mixed metal/dielectric structures have been

made use of as capacitors and resistors for many years. A new area of growth is that of integrated optic circuits in which optical signals are processed as they pass along thin surface films of dielectrics, equivalent to flat optical fibres. This is, in some ways, an extension of the already long established use of thin films as blooming coatings on optical lenses and in multi-layer interference filters. Here too there have been many recent advances and new problems uncovered particularly by the use of high energy density optical beams from laser sources. Twenty-five years ago the coating of the Mount Palomar reflector with aluminium was a major task, how many mirrors, prisms and lenses have received a thin film coating since then?

In many areas the future prospect for thin films looks good. Taking only two examples the journal reports significant advances in the thin-film-transistor and in film based solar power cells. By itself the t-f-t cannot compete with silicon technology but for a flat plate television display there is a need for a simple, cheap, mass producible, amplifying device at the end of each (x,y) coordinate. Here thin film technology can play its part and the problems that have been encountered in developing a reliable device are being overcome. The present high cost of solar cells is primarily due to the single crystal silicon used as the starting material. In order to bring the cost down to be comparable with that of conventional power supplies by 1986, as has been proposed, non-single crystal material will have to be used, and in the form of thin layers. The journal reports that thin film technologies should achieve the target on time.

It will be interesting to see what is reported in the 100th volume of *Thin Solid Films*. Perhaps by that time scientists will not be so reticent about the future. For the present the Editors are to be congratulated in giving their authors the chance to look round the field and giving us an end of term report.

Antibodies to probe development

from John K. Heath

THE favoured method in recent years for investigating the cell surface of the early mammalian embryo has been the use of antisera raised against specific embryonic tissue, or teratocarcinoma cell lines.

The best characterised of these is probably the antiserum raised against the F9 teratocarcinoma cell line (reviewed by Jacob *Immun. Rev.* **33**, 3; 1977). This antiserum reacts with a fairly restricted set of tissues; the pre-implantation embryo, the germ line and other teratocarcinoma cell lines. The fact that a particular antiserum reacts with a particular set of tissues is not in itself very informative about the role of the cell surface in the development of the early embryo. These reagents do however provide basic information on a population of cells at the molecular level, and often show that cells which are morphologically homogeneous are unexpectedly heterogeneous in their expression of cell surface antigens. F9 antiserum, for example, reacts with nearly all F9 embryonal carcinoma cells (EC cells) but with many fewer, morphologically identical PCC4 EC cells (Seisner *et al. Devl Biol.* **61**, 20; 1977). This and other observations are potentially important because 'classical' experimental embryology is usually based on histological analysis, and has generally classified cells into morphologically discrete types. This has led to a tendency to view the cells in a developing organism as moving through rigidly defined discrete stages. The use of antibodies not only allows one to extract more information on the effects of classical embryological manipulations, but poses questions which would never have arisen if cell morphology alone were used as a guide.

Conventional antisera can only be raised against those antigenic determinants which elicit sufficient response to produce detectable levels of antibody in the serum. Many potentially interesting molecules therefore escape detection. Conventional antisera are also often a complex mixture of antibodies directed against different determinants.

The recent development of 'hybridomas'—cell lines producing specific monoclonal antibodies—provides a way around these difficulties. If spleen cells from an immunised animal are fused with a myeloma cell line some of the resulting hybrid clones secrete antibody directed against the original immunogen (Kohler & Milstein *Nature* **256**,

295; 1975). Each individual clone is descended from a single antibody-producing cell in the original animal and so makes antibody directed against a single antigenic determinant. These monoclonal antibodies promise to revolutionise the study of the early mammalian embryo, amongst many other systems. They dispense with many of the technical drawbacks of conventional antisera, and allow one to find molecules hitherto undetectable on the cell surface. The first papers applying monoclonal antibodies to the study of the early mammalian embryo are now available (Stern *et al. Cell* **14**, 775; 1978; Willison & Stern *Cell* **14**, 785; 1978) and many more will doubtless follow. The results of these studies again show up unexpected differences in the expression of cell surface molecules, which might not have been predicted by classical experimentation. In making hybrids between spleen cells and myelomas one is effectively sampling the whole antibody response to a complex immunogen, and it is therefore possible to make antisera directed against very minor determinants in a population of cells. Indeed, the original immunogen used by Stern *et al.* was a preparation of lymphocytes, partially enriched for T cells. One of the clones resulting from the fusion made a product which reacted with a minor subpopulation of lymphocytes (about 2%) but reacted with EC cells to a much greater extent. This illustrates the value of screening the products of hybrids against a panel of cell types other than the original immunogen. Further investigation showed that the antibody produced by this particular clone reacted with sheep red blood cells, brain and kidney as well as with some somatic component of the testes. The species and tissue distribution suggested that this antigen was similar to Forssman antigen, and the case for this was strengthened by the observation that the antigenic determinant was carried on a glycolipid molecule.

When attention was turned to the preimplantation embryo however, the distribution of this single determinant turned out to be most unusual. The determinant first appeared on the late morula stage (16–32 cells), but could not be found on all embryos. The amount of staining increased as the trophectoderm formed, but again not all trophectodermal cells reacted with the antiserum, and there was no obvious pattern of reactivity common to all embryos. In some cases it appeared as though only one or two cells in the trophectoderm carried the determinant. If the embryo was allowed to grow out

in culture (mimicking the process of implantation) the determinant disappeared from the trophectoderm completely.

The strange distribution of this determinant does not fit in with any preconceived notions of trophectodermal formation or differentiation. It is possible that the expression of this determinant is related to the cell cycle, or that the molecule is perhaps somehow masked in the cell membrane. In any case these findings call for a number of experiments which would not even have been conceived or made possible without antibodies.

Many embryologists believe that the cell surface has an important role in development. There is, unfortunately, very little direct evidence to comfort them. Perhaps monoclonal antibody technology will not only stimulate experiments to reassure the faithful, but help to challenge a number of long held beliefs about developmental processes in general. □

History of biology at the Naples Zoological Station

from Robert Olby

Few biologists can be unaware of the important contribution which the Stazione Zoologica di Napoli has made over the years since the first visiting scientist came to work there in 1873. As Theodor Boveri declared—"How many prosperous investigations, how much joy of discovery, has this house known!" Established by the wealthy German zoologist and student of the origin of the vertebrates, Anton Dohrn, the station was intended to foster internationally the study of marine organisms. As an enthusiast for the Darwinian theory, Dohrn believed that comparative studies of the development of higher and lower marine organisms would provide the key to the phylogeny of the vertebrates. In fact the Station has been the site for researches of very wide significance in a variety of fields. They include Boveri's classic researches into nucleocytoplasmic relations and the individuality of the chromosomes in the sea urchin egg, and Otto Warburg's measurements of the respiration rate of eggs before and after fertilisation, a landmark in the introduction of physiology into development biology. Others who carried out researches at the Station were

* Held at the Naples Zoological Station Annexe on the island of Ischia from July 1–15.

John K. Heath is in the Department of Zoology, University of Oxford.

August Weismann, von Uexküll, T. H. Morgan, E. B. Wilson, Albert Szent Györgyi, Jean Brachet, Marcel Florkin and J. Z. Young.

Anton Dohrn had financed the Station from four sources—receipts from visitors to the Aquarium (then as now housed in the Station) contributions from institutes and governments who rented 'working places' for visiting members from their institutes, proceeds from the sale of preserved marine animals, and contributions from patrons. This private status of the Station came to an end as a result of reorganisation under a new Administrative Council formed in 1975. Two directors have served under this Council, Alessandro Barlaam and the present director, Alberto Monroy.

Both directors were aware of the importance of the archival material at the Station. Several years ago the archivist Christiane Groeben sorted and catalogued the scientific correspondence, photographs, and other documents with the aid of funds from the Dohrn family Foundation and the Deutsche Forschungsgemeinschaft. In 1974 an exhibition of this material was held at the Station; copies of the excellent catalogue are still available.

As the existence of this remarkable collection of some 15,000 letters is becoming more generally known Groeben's task is growing. The historical work of the Station is being expanded with the formation of a Research Group consisting of Bernardino Fantini of the Institute of Genetics in Rome, Christiane Groeben and the Station's librarian Walter Groeben.

The aim of the group is to promote the history of embryology, cell biology, biochemistry, neurophysiology and taxonomy, with special attention to the social and cultural role of research institutes. In addition to the organisation of the scientific correspondence at the Station, scientists who have had connections with the Station will be interviewed. It is planned to start with J. Brachet, A. Monroy, G. Montalenti, M. Aloisi and J. Z. Young.

At the first of a proposed series of biennial summer schools, this year on biochemical and molecular embryology*, Jean Brachet gave a spirited account of his involvement in chemical embryology. The ways in which the subject of the distribution of nucleic acids in the cell was affected by the lack of congruence between the disciplines of biochemistry and histochemistry, and the impact this had on his scientific career came over clearly.

Petrified cotton?

from F. L. Vogel and J. N. Zemel

A NOVEL material has just made its debut which provides an artificial counterpart to natural petrified materials which preserve the fine detail of the original perishable structure. Natural petrified wood for example, is formed when the original wood is infiltrated by silicious matter which converts it into a stony substance preserving the original structure. There are no comparable processes used industrially that convert organic materials to a more permanent form. The recent paper by T. L. Ward and R. R. Benerito (*Thin Solid Films* 53, 73; 1978) is therefore particularly interesting. They describe the unusual transformation of ordinary cotton fibre into a glassy material reminiscent of the permineralisation of wood.

In the Ward-Benerito process, cotton fabric is first soaked in a sodium plumbite solution after which it is dried, placed on a glassy substrate and heated to temperatures as high as 600 °C. During heating, the treated cotton initially carbonises to a black colour. As the temperature is raised, it picks up silicious material from the substrate and becomes yellow. At 600 °C the carbon skeleton is impregnated with silica and is converted to a glassy substance reproducing details of the original fabric. The authors demonstrated the results of this process with many artefacts including labels and decorations on bottles, adhesives between glasses and free standing thin films.

These results are interesting as they indicate the existence of a novel material. Still more interesting perhaps is the origin of the process which produces it. Ward and Benerito examined the composition of the plumbite-treated material using a variety of analytic techniques such as X-ray diffraction, optical and electron microscopy (TEM and SEM), ESCA, EDAX, DTA, X-ray fluorescence and atomic absorption. These studies indicated that lead was uniformly distributed in both the unheated and the transformed cotton. Furthermore, it was observed that the residual carbon concentration in the charred cotton

was six carbon atoms to one lead atom. Since lead is not known to form a carbide, this result may be taken as an indication of an interstitial or intercalation compound described in a recent popular review (Fischer & Thompson *Phys. Today* July, 1978). This conjecture is supported by the following observations.

When cellulosic materials are charred, a high defected hexagonal layered structure forms. While this is not a true graphite, it may be sufficiently similar that some degree of intercalation is possible.

The process of interstitial insertion can in itself improve the crystal perfection of the hexagonal layered structure resulting in a closer approach to a graphitic material.

The relatively low temperature of the process suggests that the diffusion occurs by an interstitial mechanism.

Silicates are known to form layered compounds, one common example of which is mica.

The mechanism suggested by this combination of facts is that intercalation of lead separates the spacing between the roughly formed hexagonal layers sufficiently to allow interstitial diffusion of the silicious materials from the substrate.

Neither the 'petrified cotton' nor the process to produce it arose in response to a stated need. As such, it is a fascinating example of a fundamental study of a technical substance. Since long term stability of cellulosic materials such as wood, paper and cotton is notoriously poor, it might be expected that permineralisation of these substances by the Ward-Benerito technique could be used. Diverse examples of this would include document preservation, converted wood as a decorative building material, or lacy *objets d'art* that could be produced no other way. As with any new material, uses will probably be found that cannot be foreseen at this early stage.

F. L. Vogel and J. N. Zemel are in the Department of Electrical Engineering and Science, University of Pennsylvania.

His modest description of his work as the correction of a series of errors was accompanied by his strong claim for the importance of his work on the transmission of information from DNA to the site of protein synthesis by long-lived RNA molecules. His statements on this subject are to be found

in his Weizmann Memorial Lecture, *The Biological Role of the Nucleic Acids*, delivered in April 1959 and published in 1960. The discovery of soluble RNA and microsomal RNA did not solve what "for the geneticist and immunologist [was] the major problem", wrote Brachet, "the mech-

anism of specific protein synthesis." Such a mechanism could be visualised if it were assumed that the "nucleus produced an intermediary substance involved in protein synthesis; there is little doubt that this intermediary is RNA...". In contrast to the *Escherichia coli* model with a short-lived messenger, Brachet's model, based on the alga *Acetabularia*, necessarily assumed a long-lived messenger, because of the long duration of protein synthesis in enucleated fragments, and this model represents more closely than the *E. coli* model, the situation in higher organisms.

Reading Brachet's Weizmann Lecture today one is struck by the scattered distribution of specific statements on the nature of 'template' (that is messenger) RNA. This may in part account for the lack of appreciation of these *Acetabularia* studies in the history of molecular biology.

The relation between chemical structure and morphological organisation was explored in several papers, most notable of which was the one by Jacques Roger of the University of Paris. He outlined the early history of the concept of an 'organic substance' as a state of chemical combination responsible for vital phenomena independent of any morphological organisation in the anatomist's and microscopist's sense of the word. The concept of a glutinous, mucilaginous, albuminoid, and later a colloidal substance can, Roger claimed, be traced back to this organic substance. Equally, the claim that the chemist can study this substance to the advantage of our understanding of vital phenomena can be traced back to eighteenth century writings on the organic substance—those of Bourguet, Buffon, Rouelle, Venel and Lamarck. In other papers the importance of the recognition of definite limits to the miniaturisation of morphological structures was stressed. Maxwell in 1875 was the first to assert that the dimensions of protein molecules set a lower limit to the postulation of such organised particles as the germules introduced by Charles Darwin in his hypothesis of pangenesis. Fantini emphasised the novelty of the concept of three-dimensional, specific structure in macromolecules determined by sequence, and he contrasted this with the vaguer conception of shape to be found in colloid science.

The establishment of this Research Group in Italy is an important event in the history and philosophy of science. Hitherto work in the subject has tended to be dominated by Anglo-American activities. The programme initiated by the Research Group should not only act as a catalyst to the growth of the subject in Italy, but should also stimulate such work in the area of the

life sciences, as befits a group associated so closely with the international activities of the Zoological Station. □

Globular clusters

from Virginia Trimble

THE globular clusters comprise the oldest stellar population readily available to us for study. They ought, therefore, to be able to provide the answers to various questions in galactic and stellar formation and evolution—if only we knew which questions to ask. The chief difficulty lies in deciding whether they are the rare (about 10^{-4} of the observed mass in the Universe) survivors of a population of once-common, fundamental building-blocks from which larger units (galaxies and clusters) have arisen, or the products of early fragmentation in previously-existing gas clouds that we might call protogalaxies.

Uncertainty on this basic point underlay and sometimes befuddled discussions of new observations and calculations at a recent NATO Advanced Study Institute on Globular Clusters.* For instance, the average heavy-element abundance of a population of globular clusters increases with the mass of the galaxy to which it is attached (S. van den Bergh), and, within at least the Milky Way and the Andromeda Galaxy, abundances range systematically from nearly solar at the centre, through a steep decline 5-10 kpc out, to one-twentieth of solar or less in the halo (with large scatters at all positions; L. Searle). But is this trying to tell us something about how star-formation rates (and, therefore heavy element production) depends on gas density or something about how dynamical friction juggles units of varying mass and degree of central concentration?

Dynamics of stars within individual clusters can be considered almost without regard to their origins, because at least the inner parts are relaxed. The identification of seven X-ray sources (including five bursters; W. Lewin, G. Jernigan) with globular clusters lends extra urgency to calculations of core evolution and collapse (L. Spitzer), although recent estimates of the surface area required to produce the bursts and the relative timing of optical and X-ray emission in one burst now strongly suggest that the source is an accreting neutron star rather than a massive black hole formed by core collapse. Core evolution may still have

to be invoked to put a neutron star into a suitable X-ray-producing binary system, as it becomes increasingly clear that the clusters are deficient (relative to stars in the galactic disk, at least) in binary systems over a considerable range of parameters (J. Gunn, R. Griffin, M. Liller, E. Budding). But all is not lost, even if core collapse never occurs (J. Katz), as it may be possible to get the observed X-ray flux from single neutron stars occasionally passing through the stellar winds of red giant stars (A. Fabian). The amount of ambient gas implied by this is well below the 0.1-1.0 M seen or set as upper limits from HI and HII studies of several clusters (G. Knapp, W. Liller). Some of these limits are, however, uncomfortably low for standard theories of mass loss from evolving stars and gas escape from clusters (D. Faulkner).

Progress has been made on several traditional, vexing, rather technical issues. The wide giant branch in ω Cen is undoubtedly to be attributed to real abundance variations, and because CN line strength is generally correlated with Ca, Fe, and Sr abundances (J. Norris), the variations must have been intrinsic to the gas from which the stars formed, and not just produced by mixing within individual giants. Real variations in CNO abundances occurring among and within other clusters (especially 47 Tuc; A. Rodgers), are not always uniquely correlated with variations in Fe and heavier elements (J. Frogel, E. Persson), and may also be primordial (R. Kraft); but they are not the whole answer to the traditional 'second parameter' problem.

The second parameter(s) is whatever is responsible for the lack of the theoretically-expected correlation of the appearance of a cluster's HR diagram with its heavy element abundance. The most conspicuous effect is the occurrence of both red and blue horizontal branches in metal-poor clusters, especially in the outer parts of the galaxy (R. Zinn), when only blue ones would be expected. High CNO (either primordial or mixed up from the core) would cure this, but CNO cannot deal (V. Castellani) with a more subtle effect seen in some far-halo clusters (R. Schommer) in which the red-giant branch is too red for the metal abundance implied by the main-sequence turn-off point and integrated cluster spectra. HR diagram morphology is also affected by helium abundance, cluster age, mass loss from red giants, and stellar rotation. It will probably be necessary to include the contributions of at least two 'second parameters' to match the full range of observed HR diagrams. Rotation is apparently also important (A. Sweigart) in finally making it possible to under-

*Held on 7-18 August at the Institute of Astronomy, Cambridge.

stand how processed material can be mixed up from the hydrogen-burning region to the surface of low mass stars by means of meridional circulation.

No consensus now seems possible on the meaning (or, in some cases, even the reality) of colour and abundance gradients within clusters other than ω Cen (K. Freeman; M. Chun; G. Da Costa). The question of whether or not the absolute brightnesses of RR Lyrae variables are correlated with their metal abundances is 'controversial.' It is important because these stars are one of our standard candles, whose brightness partially determines the extragalactic distance scale, and so Hubble's constant and the age of the Universe. W. Liller

Virginia Trimble is at the Astronomy Program, University of Maryland.

and V. Clube strongly advocated a relationship (partially based on recent photometry by B. Carney) in which the RR Lyraes in clusters of lowest metal abundance are about one magnitude fainter than those in clusters of high Z. A constant brightness for these stars, independent of cluster composition, was equally strongly supported on both observational and theoretical grounds by P. Demarque, R. Kraft, and F. Hartwick.

The various problems of globular cluster astronomy are probably in as good shape as we can expect, considering that (although some of the clusters were recorded by Messier) the first classification of them by radius and central concentration was begun only about 50 years ago by H. Sawyer Hogg, who was an active participant at the Institute. $\square$

infected cultures showed the presence of about three copies of non-integrated hybrid genome per cell. Some copies might have integrated with the host DNA and been maintained as such but the evidence for this was not conclusive. Infected monkey cells, which with wild type SV40 support the production of mature virus, were found to contain amounts of nonintegrated, superhelical hybrid DNA which was stably propagated when the cells were cloned.

There are several advantages to this system of nonlytic propagation using a crippled vector. First, the recombinant DNA is never expressed as an infectious virus particle simply because it does not possess the necessary genes. This satisfies some of the safety considerations involved in this type of work. Second, since assembly of a complete particle is not needed, the amount of DNA that can be 'carried' on the SV40 vector is probably increased, and third, the host cells remain viable, which offers the chance of long term studies or the maintenance and expression of 'foreign' DNA sequences in a mammalian system.

Hamer *et al.* looked for expression of the bacterial gene in the original lytic infection and found that although the sequence was transcribed into RNA, no functional suppressor tRNA was detectable. This is not surprising in view of the different types of processing of tRNA that probably take place in bacterial and eukaryotic cells (Knapp *et al. Cell* **14**, 221; 1978; O'Farrell *et al. Nature*, **274**, 438; 1978). This may not be a problem when the gene 'insert' is from a more closely related donor. Rumour has it that correct transcription and expression of globin genes cloned in an SV40 vector in mammalian cells has been achieved in Paul Berg's laboratory at Stanford.

There are a variety of sequences that could usefully be worked on in a system of this kind, but many of them will probably have to wait until more has been done to reduce the possible hazards of working with a tumour virus. The vector in these experiments could still transform cells, and it may be necessary to remove this ability before the SV40 is sufficiently 'crippled' to use with genes that might confer a selective advantage on the hybrids.

Other routes exist for getting genes into mammalian cells, for example, by cell fusion and selection (Szybalski *et al. Natn. Cancer Inst. Monogr.* **7**, 75; 1962; Littlefield *Science*, **145**, 709; 1964) and such genes may be expressed in adult animals (Illmensee *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 1914; 1978). But in terms of simplicity and flexibility the tumour virus vector could be a winner. $\square$

Bacterial gene into monkey cells

from John Jenkins

ONE of the long term aims of genetic engineering recently came a step closer to reality, with the stable propagation in mammalian cells of a hybrid DNA molecule containing a mammalian tumour virus chromosome and a bacterial gene. The successful development of such vectors for introducing and propagating genes in mammalian cells offers the hope of eventually being able to study the control of expression of eukaryotic genes in a system not too far removed from their natural environment. Even further in the future is the possibility of using such vectors to introduce particular genes to correct inborn genetic defects.

The idea itself is not new. In 1972, Jackson *et al. (Proc. natn. Acad. Sci. U.S.A.* **73**, 2904; 1972) described the construction of a hybrid molecule from simian virus 40 (SV40) and bacteriophage λ DNA, and such hybrids can replicate in suitable host cells (Ganem *et al. Cell* **7**, 349; 1976). The problem is that replication of the hybrid virus kills the host. A new development gets round this problem by tailoring or 'crippling' the SV40 so that the genes responsible for cell death are cut out before the hybrid is made.

SV40 can behave in two different ways when it infects a cell, and its genome can be divided into two regions on this basis. In rat cells, the entire virus genome is inserted into the host

chromosome and the cells change many of their growth characteristics. This transformation requires the expression of only about half the SV40 genome making up what is known as the early region. The second type of infection, of monkey cells for instance, requires expression of most of the genome. In this case, the remainder of the viral genes are functionally expressed and about 36 h after infection mature virus particles appear, followed by the lysis of the host cells. Cell types that support this lytic cycle of infection are termed permissive, while those which transform but fail to produce mature virus are called nonpermissive.

In order to cut out the genes responsible for lytic infection, (Hamer *et al. J. molec. Biol.* **112**, 155; 1977) cleaved the circular virus DNA at two points within the late region, using the restriction enzymes *HpaII* and *EcoRI*. The large fragment from this, containing the origin of DNA replication and the early region genes, was ligated to a DNA fragment containing an *E. coli* tRNA suppressor gene. In order to get large amounts of the hybrid DNA it was necessary to first grow it up in monkey cells in the presence of a helper virus which possessed functional late region genes. Purified hybrid DNA from this lytic cycle was then used in the present series of experiments (Upcroft *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 2117; 1978).

The hybrid DNA was found to transform nonpermissive rat cells, and analysis of total cellular DNA from

John Jenkins is working in the Nucleic Acid Laboratory, Imperial Cancer Research Fund, London.

Forty years of plant mitochondriology

from A. L. Moore

It has taken approximately 40 years since the first paper was published describing their oxidative capacities for a symposium to be held specifically devoted to plant mitochondria.*

Although the cytochromes of plant mitochondria are spectrally and functionally similar to those of animal mitochondria, there is still confusion about the role of the multiple *b* cytochromes in electron transport. B. T. Storey (University of Pennsylvania, Philadelphia) suggested that cytochromes *b*-556 and *b*-560 are part of the respiratory chain whereas cytochrome *b*-565 only associated with the main chain in the energised state and in the presence of antimycin A. This suggestion was based upon the kinetic behaviour of *b*-565, in particular its complex oxidation/reduction kinetics during coupled substrate oxidation. However a few papers were presented which disagreed with this interpretation and it was suggested that a possible Q-cycle mechanism could explain the complicated nature of *b*-565 reduction under oxidative conditions.

P. R. Rich (University of Cambridge) gave a detailed analysis of the paramagnetic centres associated with higher plant and *poky N. crassa* mitochondria. Of particular importance was the finding that no EPR-detectable component was directly attributable to the alternative oxidase and furthermore it was suggested that there is no evidence for a direct involvement of iron sulphur centres or transition metals in a paramagnetic state in the terminal oxidation system. Although the HiPIP and ferredoxin-type centres are analogous to their mammalian counterparts, an EPR signal characteristic of a high-spin ferric iron with a *g* value at 4.3 was independently reported by Rich and M.-F. Henry (University of Amsterdam). Henry presented evidence in favour of this iron-containing protein's being involved in the cyanide insensitive respiratory pathway although the redox behaviour of this signal under conditions in which the alternative oxidase was operating was questioned. Obviously further work on the function of this component is required before its possible role in alternative oxidations can be better understood.

The topic which generated much interest and led to lively round-table discussions was the relationship between the malate oxidoreductases and NADH dehydrogenases. The pro-

cess of malate oxidation is much more complex in plant than in animal mitochondria. Malate can be oxidised by two malate oxidoreductases and the NADH produced may be oxidised by at least four different NADH dehydrogenase systems. One of these dehydrogenases is located on the outer surface of the mitochondrial inner membrane.

Although there is general agreement that the oxidation of malate is mediated by an NAD⁺-linked malic enzyme and malate dehydrogenase, the exact location of these enzymes is still controversial. J. M. Palmer (University of London) took the view that the oxidation of malate can provide NADH for oxidation by both the internal and external NADH dehydrogenases and that malate reduces external NAD⁺ primarily by the activity of externally located malic enzyme and malate dehydrogenase. In contrast, however, J. T. Wiskich (University of Adelaide) supported the view that the external NADH dehydrogenase was not involved in the oxidation of malate in the absence of added NAD whereas in its presence a transmembrane transhydrogenase has been postulated to operate, which is considered to transfer reducing equivalents from internal NADH to external NAD thus connecting internal malate oxidation to the external dehydrogenase. D. A. Day (University of California) presented evidence on the malic enzyme distribution in potato mitochondria from which he concluded that malic enzyme is not present in the intermembrane space of these mitochondria and furthermore that all malate oxidation occurs in the matrix. Perhaps in this respect, the most interesting findings reported at this symposium were the detailed investigations of M. Neuburger (Université de Grenoble) on the transport of NAD⁺ through the inner membrane of purified mitochondria. Convincing evidence was presented which indicated that highly purified intact plant mitochondria possess a NAD-translocator. Most workers readily agreed that the existence of such a carrier would explain many of the conflicting reports in the literature on malate oxidation and the further characterisation of this carrier is eagerly awaited.

The sessions on the molecular and cellular aspects of cyanide resistant respiration attracted considerable attention. The exact nature of the alternative oxidase has remained elusive for many years. However, as W. D. Bonner (University of Pennsylvania, Philadelphia) pointed out, a considerable amount of evidence has accumulated which allows a fuller understanding of its branchpoint from the main respiratory pathway and the nature of the products of the alternative oxidase with

oxygen. Bonner suggested that a modified protonmotive ubiquinone cycle satisfies the kinetics of cytochrome interactions, and that the alternative pathway accepts electrons non-protonmotively from this cycle. This proposal suggests that a pool of ubiquinone in the succinic dehydrogenase region of the respiratory chain is performing as the branchpoint for the alternative pathway. Bonner concluded that the alternative oxidase could either be a species of ubiquinone or an EPR-silent metalloprotein that facilitates the reaction of the ubiquinone species with oxygen. In this regard a great advance in our knowledge of the nature of the alternative oxidase was obtained from the studies of Rich and S. Huq (Imperial College, London) who presented results on the isolation and partial purification of the alternative oxidase from *Arum maculatum*. Both workers used a hydroxamic acid-sensitive quinol oxidation as an assay for the oxidase. Remarkably, Rich found that in a deoxycholate solubilised preparation the quinol oxidase activity remained very stable, which seems to suggest that the lability of the oxidase in intact mitochondria may be due to the connection between the dehydrogenases and oxidase, and not the alternative oxidase itself. Both preparations contained minimal amounts of cytochromes *aa₃*, *c* and *b*. It was of particular interest to note that the overall product of oxygen reduction by the quinols was water.

A. M. Lambowitz (University of St. Louis) reviewed the current status of the biosynthesis of the alternative oxidase in *Neurospora* mitochondria. An important development in this area has been the isolation of antimycin-sensitive mutants with defects in the biosynthesis of the alternative oxidase. All cytochrome system activities seem unaffected in the mutants and the only apparent defect is in the induction of the alternative oxidase. Lambowitz suggested that the results indicate that there are at least two polypeptides unique to the alternative oxidation system. □

Erratum

In the article 'Halogenated hydrocarbon effects' (*News & Views* 274, 533; 1978), in the last paragraph, column 1, on page 534, the first line should read "Both the PCBs and the polybrominated biphenyls (PBBs) induce hepatic effects". In the second paragraph, column 2, line 4 ff. should read "Poland . . . believes this to be a receptor for TCDD and consequently for other inducers of aryl hydrocarbon hydroxylase . . .".

*The First International Symposium on Plant Mitochondria was held at the Luminy campus in Marseilles on 31 July-4 August.

review article

ASSESS II: a simulated mission of Spacelab

H. M. Wegmann¹, R. Hermann¹, C. M. Wingett², M. de Muizon³, D. Rouan³, P. Léna³, J. Wijnbergen⁴, H. Olthof⁵, K. W. Michel⁵, Ch. Werner⁶, F. Melchiorri⁷, B. Melchiorri⁷, V. Natale⁷, R. Falciani⁸, L. R. Smaldone⁸, E. Bussoletti⁹, J. Crawford¹⁰, P. Rothwell¹⁰, M. Taylor¹⁰, J. E. Beckman¹¹, D. Dale¹¹, J. Schmitt¹¹ & J. de Waard¹²

ASSESS II, a joint exercise of NASA and ESA, was set up to enable scientists to become accustomed to an atmosphere-free, gravity-free working environment. This simulation of Spacelab conditions has provided new data and a valuable insight into the possibilities and limitations of such a mission.

IN THE 1980s many scientists in Europe and the USA will be able to fly experiments in space using the Spacelab now under development by the European Space Agency (ESA). The experiments will cover a wide range of disciplines and will often fly on a single mission together with equipment for engineering and industrial applications. It is important for would-be experimenters, and ESA, to learn early those operational techniques specific to Spacelab which will enable scientists to gain maximum benefit from its advantages of an atmosphere-free and gravity-free environment.

In 1975 NASA and ESA conducted a joint exercise, ASSESS I, using a Convair 990 research aircraft, the Galileo II, belonging to NASA's Ames Research Center, in a preliminary simulation of a Spacelab flight. Four scientists were confined to the aircraft for a week, during which six research flights were conducted, with a multi-experiment payload (three USA and three European), aimed at astronomy and stratospheric studies. The results of ASSESS I were encouraging, in that they showed how experimentalists with only a few weeks' specialised training could act as proxy operators (payload specialists) for a range of experiments not necessarily from their own fields of research. However, the project was assembled rather hastily, and was not as realistic a simulation as desired. Experiments were not organised ergonomically into a payload, making the work of the payload specialists exceptionally difficult. No attempt was made to use a common integration site, with specially prepared ground support equipment, and the ADDAS onboard computer system for handling scientific data could not be used satisfactorily because of lack of time to prepare and check software.

ASSESS II, flown in mid 1977, aimed to improve the realism of the simulation, and provide another chance for scientists to acquire new data. The same aircraft was used, with six American and six European experiments on board, run by four payload specialists. The mission was longer, with nine research

flights each of 6-h duration carried out in a 10-d period. Payload specialists were confined within the aircraft, or in a juxtaposed sleeping trailer, communicating to the outside world only by telephone or radio. Here we describe how the mission was organised, and present some of the initial data from the European experiments.

Choice of experiments

The ESA selection committee based its choice of experiments to fly on (1) its scientific value; (2) the state of experimental readiness; there was just over a year between experiment selection and flight, so it was preferable to use an experiment which did not have to be built up from scratch; (3) its ease of operation: using payload specialists to run three experiments each, some highly complex, meant avoiding apparatus with many fine tuning adjustments, switches to throw continually, and widely separated pieces; and (4) the similarity to the types of experiments envisaged for Spacelab.

The full complement was chosen for mutual compatibility to avoid, as far as possible, clashes in the mission timing and trajectory plans. The selected experiments were: A threefold infrared astronomy experiment, based on a 32-cm infrared telescope (Meudon). This carried a continuum photometer for observing interstellar dark clouds (Groningen), and a line spectrometer for interstellar sulphur in HII regions (Garching); a television camera to study infrared airglow from noctilucent terrestrial clouds (Southampton); a sub-millimetre spectrophotometer to measure the Sun's chromospheric brightness temperature (Naples-Florence); a LIDAR system to measure aerosol distribution in the troposphere (Oberpfaffenhofen); medical probes to study diurnal and stress-induced behaviour of the payload specialists (Bad-Godesberg); and test equipment to study the electromagnetic environment, and help remedy earthing problems (Noordwijk). (This was operated by the crew and used also on behalf of the USA payload.)

Italian, French, Dutch, German and British groups were represented as for ESA satellite programmes, and as intended on Spacelab.

Experiment preparation

Build up of the ASSESS II experimentation was begun at experimenters' home institutes in late 1976; the payload specialists received two to three weeks' initial training on

experiment in this period. In January 1977 all the experiments were gathered at the ESA/SPICE facility at the DFVLR, Porz-Wahn near Köln. Here they were integrated electrically and mechanically into a mock-up of the aircraft, and simulation tests of the European half of the payload were carried out. It was convenient for the principal investigator teams to attend for long periods, but the payload specialists who were on the spot all the time increasingly handled the equipment. During this period they were able to write their detailed procedures for installing and operating the experiments on the aircraft.

The simulation was very realistic, demanding continuous manning of the experiments and of a control room designed and operated as a replica of that at Ames. Two sets, of four 'flights' each, tested the skills of the payload specialists, and their interaction with the ground teams. After this simulation the experiments were moved to California, where the whole (including USA) payload was put together on the ground at NASA Ames, then installed in the aircraft and flown.

The data flights

In late May 1977 the simulation mission of nine flights was performed, followed by a set of 'principal investigator flights', during which the Spacelab-like conditions were relaxed, and more personnel went on board to assist with each experiment. The nine simulation flights took place on schedule with minimum intervals of less than one day for maximum loading on the payload specialists. Communication during the mission was via a control centre, in which the teams running the flight and payload operations lived. The scientists on the ground could

talk to the payload specialists for limited periods, about two hours per day, to advise on experiment preparation in the light of information from the previous data-take. A TV camera enabled some visual information to be passed 'upwards' to the aircraft (only available when on the ground) while a regulated allowance of data was removed from the aircraft between flights, corresponding to a bit rate which can be accomplished by planned telemetry from the shuttle. In practice communication during actual flights was difficult—this was one way in which conditions were significantly worse than those anticipated for Spacelab. Another difference was the successive takeoffs, landings, and refuellings, with their disruptive effects. Figure 1 shows a typical trajectory for a night flight, and gives an idea of the distribution of activities for the European experiments during such a flight. The LIDAR and the solar experiment were kept running for most sections of all the trajectories, providing routine data on the Earth's atmosphere. Two night flights over the Pacific viewed southerly astronomical objects, and the day flights included prolonged manoeuvres over cities and peculiar terrains, for LIDAR and for the USA payload, which was mainly Earth-resource orientated.

The individual experiments, and their results will be presented elsewhere. Here we indicate the organisational complexity of the project, and the payload specialists' tasks.

Infrared astronomy

A 32-cm aperture infrared telescope which had flown on ASSESS I, carried two instruments, a 4-band photometer spanning the wavelength range 31–196 μm , and a Fabry-Pérot

Fig. 1 The trajectory of an ASSESS II night-time flight over the Western USA. Data were taken throughout each 6-h flight, while preparations and post flight checks took between 6 and 10 h longer. Flight tracks for Purple 1, 21 May 1977: solid line, original plan; dashed line, revised plan; all times UT.

Fig. 2 A scan of the dark interstellar cloud Sharpless 140, obtained with the Groningen photometer in the waveband 115–196 μm (TII filter). The abscissa registers a scan amplitude of 29 arc min in RA using a diaphragm of 4.5 arc min diameter.

line spectrometer, both cryogenically cooled. The payload specialist could switch between them using a flip-flop mirror in the telescope. A sensitive TV camera facilitated finding and locking onto infrared position, by serial spot-follower and gyro-stabilised control loops. These experiments were run throughout the mission by one payload specialist.

Figure 2 shows a typical output scan; new flux maps of the molecular clouds S140(A), R Cr A, and M17 were built up from such scans, and previous measurements of the galactic plane^{2,3} and of sky noise⁴ were revised with increased precision. Spectra at the 33.6 μm wavelength of SIII emission with the Fabry-Pérot system were, however, inconclusive.

Fig. 3 Mass concentration of aerosol particles (in mg m^{-3}) as a function of altitude over a portion of the San Francisco Bay area, measured by the LIDAR experiment on ASSESS II.

Solar brightness temperature

During daytime flights a Michelson interferometer was fed by a gyro-stabilised coelostat, giving solar spectra in the range 300 μm –2 mm wavelength. The aim was an absolute determination of the chromospheric brightness temperature to within 250 K, for use in physical modelling. The equipment was also operational on all other flights, yielding terrestrial atmospheric emission spectra varying with latitude and altitude, and examining submillimetre sky anisotropy over a 2° field, aimed at the cosmic background radiation⁵.

Fig. 4 OH airglow seen in the form of narrow stripes with the TV camera system at 700–900 nm.

Lidar

Figure 3 shows an aerosol distribution diagram for an area south of San Francisco. It shows the effectiveness of the airborne LIDAR, which obtained such data over urban areas (Los Angeles basin and San Francisco Bay) and over very varied terrain (Mojave desert, Rocky Mountains, and the Central Valley of California). The already standard LIDAR technique of measuring the time of flight of back-scattered pulsed near infrared laser radiation emitted from the aircraft, was calibrated using the simultaneous data of Dr P. Russell, taken from the ground at the Stanford Research Institute.

Airglow TV

Mesospheric airglow from the OH layer, ~85 km above the Earth was studied for structure due to winds, atmospheric tides, and gravity waves. The TV technique used was a development of that flown on ASSESS I (ref. 6), recording images in the 700–900 nm waveband every 0.15 s. This compares with 5–10-min photographic exposures from mountain sites^{7–9}. Figure 4 shows narrow-banded mesospheric structures, observed during ASSESS II. During the mission broader bands were commonly seen, also patches, and V-shaped structures. Amid this variety of geometrical patterns, banded structures with tens of km periods and maximum

Fig. 5 A survey, abstracted from the medical experiment data, of the temperature rhythms for the six payload specialists (two USA, two European, and two European ground back-up) working on the ASSESS II mission.

extension around 700 km were frequently prominent. The latter seem too small to fit gravity wave predictions¹⁰. The data, a clear improvement on ASSESS I, show that tropospheric storms can cause mesospheric airglow pattern changes, and provide evidence for multiple layers in the airglow, from sets of bands at fixed common angles.

Medical experiment

The medical experiment was aimed directly at Spacelab. Each payload specialist (two Europeans and two Americans flying, plus two European back-ups on the ground) was fitted with a rectal temperature probe, and ECG (electrocardiogram) electrodes, recording continually on to miniature tape-recorders carried on a belt. During sleep the EEG (electroencephalogram) was measured and similarly recorded. Every three hours, except during sleep, a urine sample was collected and stored frozen for subsequent analysis of hormones and electrolytes.

A global look at the temperatures of the payload specialists (PSs) is given in Fig. 5, for two days pre-flight, nine flight days, and two post-flight days. Effects of slipping the working routine

against the 24-h day are seen in the drift of the diurnal maxima and minima, (see PS 1, 5 and 6); the increasingly broken rhythm (see PS 3, also 2 and 4) is due to poor sleep. Full analysis of the 10 parameters recorded will be valuable for planning activities and routines for Spacelab.

Experiment grouping

The infrared astronomy experiments, comprising five experiment racks and the telescope, were run by one payload specialist while the LIDAR, Airglow and Solar experiments were run by the other. Ergonomically this worked quite well, as the latter three were controlled mainly from a centralised panel, and the effort demanded for each group was roughly equivalent. Although considerable progress in reducing trivial switch-throwing had been made since ASSESS I, further automation would have undoubtedly reduced stress on the payload specialists.

Data management

The airglow, medical, LIDAR, and astronomical photometer experiments were either entirely self-contained in data storage

and quick-look analyses or used the ADDAS system only as a back-up. The other experiments relied on ADDAS as their main data-processor; however, time and funding limitations caused experiment-ADDAS interfacing to become a major problem immediately before launch.

Lessons

Some clear lessons have been learned from the ASSESS programme, which can be used as a series of general guidelines for would-be Spacelab experimenters; the most evident are given below.

(1) Keep interfaces with Spacelab simple. This includes the mechanical, the electrical, and signal processing. The latter is particularly interesting, as Spacelab will provide a central data management system (CDMS) analogous to the ADDAS used in ASSESS II. Self-contained data gathering, processing and storage by any single experimenter not only gives him practical flexibility, and eases competition for scarce CDMS memory, but allows him to develop software at his own pace and with his own personnel during the build-up to a flight. The CDMS should be used to send highly selected data by telemetry to the ground, allowing a team to analyse problems for which the payload specialist has no time during the mission.

(2) Electromagnetic cleanliness is important. ESA set precise earthing and shielding standards for the European experimenters. These were not mandatory during ASSESS II for the US experiments, which therefore had far more problems with electromagnetic interference. Failure to adopt such standards could be costly.

(3) Experience is an effective way to learn. Those experiments which had been aboard ASSESS I gave a data yield nearly an order of magnitude greater when flown this time. This indicates that airborne missions are highly cost-effective ways for scientists to improve their potential rewards from Spacelab flights. Similar criteria apply to the management teams who feel that their direct experience on ASSESS would be valuable in organising Spacelab.

(4) For payload specialist efficiency unified control panels for groups of experiments must be built up. Diverse experiments will therefore need to be integrated, on the ground, into a single payload and also to check-out cross-talk effects, and because any payload work on board the shuttle will be costly

and complex. From a European viewpoint the build-up of a team of engineering experts at an integration site ('SPICE') within an ESA member state was shown to be practical. This centre gave a much better training scheme for payload specialists than the method used during ASSESS I, of sending payload specialists only to experimenters' home institutes for training purposes.

(5) Time and capability for *in situ* diagnosis and repairs to experiments in flight is very limited, when one payload specialist may have care of around 20 separate payload elements. A useful approach is to predict the probability of key failures, and build in redundancies as well as using modular experiment design, with replaceable key back-up units. In spite of problems, the value of the payload specialists was shown by the quantity and quality of the data obtained on ASSESS II, and clearly, using the shuttle with payload specialists will enable many more experimenters to use space platforms, with a much wider range of experiment categories than can participate in conventional satellite programmes. One result of ASSESS II is to show that the comparable complexity needed to build and operate airborne experiments, the lead times required, and the relationship to laboratory instrumentation, make aircraft programmes very suitable preparation and training for Spacelab. This is true for the experimenters, for the payload specialists, and also for the management teams. Whether ASSESS I and II have provided enough experience for NASA and ESA managements, and whether or not this is used, only time and the Spacelab programme can tell.

We thank staff members of NASA Ames Research Center, Informatics Inc., NASA Marshall Spaceflight Center, NASA Kennedy Space Center, NASA Headquarters, ESA-SPICE, DFVLR Porz-Wahn, ESA Headquarters and ESA-ESTEC who contributed to the success of this mission.

Formation of the early Earth regolith

M. D. Nussinov & A. A. Vekhov

Academy of Sciences of the USSR, Space Research Institute, 117810 Moscow, USSR

Appropriate physical conditions for the origin of life could exist on the relic regolith grains. A regolith of this type could be formed on the entire surface of the Earth under the effect of space factors in the early epoch which was characterised by a strongly rarified atmosphere. In the subsequent epoch with a denser atmosphere and suitable conditions for the first occurrence of liquid water droplets such grains had to acquire a considerable biochemical activity.

EXISTING hypotheses about the origin of life on the Earth are based either on the initial conditions of the planet or on those of space, and can be subdivided into two distinct groups. The first such group assumes that the bioevolution started in primitive water bodies¹—especially in the course of submarine volcanism², whereas the second group supports the concept of the formation of prebiological material on the surfaces of interstellar dust grains which were later transported into the Solar System and to the Earth^{3,4}. The hypotheses of the first and especially of the second group have been severely criticised^{5,6}. However, several objections can be avoided if a new hypothesis

were considered based on the following conditions necessary for 'the origin of life platforms' (developed and formulated in refs 1, 5, 7): (1) large specific area of grains (with appropriate macro- and micro-porosity); (2) immersion of grains into the water medium; (3) free energy available for biochemical reactions; (4) global character of the appropriate conditions; (5) large (in the geological sense) time span for the events; and (6) absence of powerful inhibiting factors. None of the existing hypotheses satisfies these conditions completely.

We put forward here a hypothesis with initial conditions that cannot fully be related either to the first or to the second type of hypotheses and which are 'on the border' between planetary and space conditions. According to our hypothesis, the regolith grains which formed on the early Earth's surface during an epoch of a strongly rarified atmosphere could serve as the platforms for the origin of life. We designate this type of regolith as relic or *R*-regolith. In contrast, an airless planet's regolith (such as the Moon's) will be designated *M*-regolith. We shall show that the conditions for the formation of each of these two types of regoliths are different.

Together with cosmic electromagnetic and corpuscular irradiation, meteorite bombardment is known to be one of the main exogenic factors responsible for the formation of a planet's regolith. We believe that the most interesting situation arises on a planet almost completely lacking an atmosphere ('nearly atmosphereless'). In this case the bulk of a micro-meteorite flux reaches the planet's surface with an appreciable loss in the mass and velocity of particles whose final distribution function $I_f(m_i, v_i, P)$ is transformed from the initial case $I_i(m_i, v_i, P)$ so that in the atmosphere pressure (P) range, from $P_1 \sim 10^{-7}$ atm to $P_2 \sim 10^{-4}$ atm, mostly small particles with velocities $v_i < 10^5$ cm s $^{-1}$ impinge on a planet's surface⁸. When $P > P_2$, $I_f \rightarrow 0$, extremely quickly, whereas at $P < P_1$, ($I_i - I_f \rightarrow 0$) but much more slowly. However, the penetration of space electromagnetic and corpuscular radiations through a rarified atmosphere is significant. For instance, a CO₂ atmosphere with $P \approx 10^{-5}$ atm (which has a penetrability equivalent to a 6.5×10^{-3} cm thick CO₂ solid filter) is rather 'transparent' to the fluxes of UV and X-ray radiations and insignificantly detains charged particles with energy $E > 0.1$ MeV (ref. 9).

Hence it seems that the regolith-forming conditions on the surface of a nearly atmosphereless planet will be different to those on an atmosphereless one. Hence, a different regolith forms on each of these planets.

It is interesting to consider the problem of *R*-regolith formation in conjunction with the investigations of Meadows¹⁰ and others which establish the existence of an atmosphereless period on the Earth (after loss of the primary H₂-He atmosphere) which was followed by a period of gradual accumulation of a new atmosphere. At first, the new atmosphere consisted mainly of CO₂ and H₂O vapours—the products of mantle degassing and volcanic activity. Since then the present atmosphere has been developing. More than 4,000 Myr ago there was a crucial moment in this evolution. When the atmospheric pressures reached $P \approx 10^{-3}$ atm and the Earth's surface temperature became $T \approx 273$ K (triple point for water), the appropriate conditions for liquid H₂O occurrence were created¹¹. Before this, water desublimation resulted only in the formation of low mobile hard ice mounds and in hoarfrost. The epoch of smaller atmospheric pressures and temperatures, directly adjacent to this period, satisfied the conditions necessary for *R*-regolith formation. Therefore, we assume that by the time that water condensed, the Earth's surface was covered with an *R*-regolith which predetermined the directions of geochemical and prebiological evolutions.

Let us consider certain physical properties of *R*-regolith and, primarily, its macroporosity determined by an average grain-size distribution which, in its turn, is determined by the correlation between the rates of the two competing processes of comminution and aggregation. As for *M*-regolith, the process of comminution in *R*-regolith occurs under the impacts of micrometeorites, whereas aggregation results from cohesion

and agglutination. In a rarified atmosphere the specific energy of an impact $E_i = v_i^2/2 \approx 10^9$ erg g $^{-1}$ is sufficient only to break up the grains, and not to melt them ($E_m \approx 10^{11}$ erg g $^{-1}$ (ref. 9)). Consequently, the *R*-regolith will not contain glassy particles and glassy surfaces which are characteristic of the *M*-regolith¹². On the other hand, gas from a rarified atmosphere is immediately adsorbed on the split-off surfaces of grains which decreases drastically their aggregation due to the deterioration of the cohesive properties of grains by several orders of magnitude. Therefore, the competition between comminution and aggregation will favour the former. Consequently, the average grain-size distribution in *R*-regolith will decrease, whereas its specific surface S_R and hence its macroporosity will increase from the minimum value $S_M \approx 0.1$ m² g $^{-1}$, characteristic of *M*-regolith¹³, by one or two orders of magnitude.

Microporosity should be regarded as another peculiar feature of the *R*-regolith. Micropores result from the radiational and structural defects (tracks, dislocations, and so on) in the volume of the grains. The presence of micropores in the grains of *M*- and *R*-regoliths is due to the absorption of hard cosmic electromagnetic and corpuscular radiations. However, such defects are hardly detected in the Moon's regolith because the micropores in its grains are continuously destroyed by high-velocity micrometeorite impacts (which cause shock waves in the grain volume and melt grain surfaces) and due to sharp diurnal fluctuations of the surface temperature¹³. This has been confirmed by simulation experiments when the Moon's regolith was irradiated¹³. This situation is very similar to the conditions existing on a nearly atmosphereless planet.

The *R*-regolith micropores had to contain gas resulting from the photodecomposition of atmospheric gases (dissolved in the volume of grains) as well as rock- and mineral-forming oxides. This gas in micropores had to be in a physically adsorbed state and enriched with O₂ which accounted for about 50% of the specific weights of most rocks, minerals and some atmospheric gases.

Now, let us consider the conditions of chemical evolution which existed on the Earth's *R*-regolith during the time of liquid H₂O condensation on the planet's surface. The gas accumulated in the micropores of the grains and adsorbed on the macropores, had to escape outside by the Rebinger effect (adsorptional decrease in strength¹⁴) and by displacement desorption with water, which has the greatest energy of desorption ($E_a = 10$ –12 kcal mol $^{-1}$) relative to other common gases ($E_a = 3$ –8 kcal mol $^{-1}$ (ref. 9)). By releasing gas from the pores of *R*-regolith, water partly occupied its place and in the near-surface atmosphere, probably, initially O₂ and then other gases (CO, N₂, and so on) were evolved. However, the atmosphere remained fairly transparent to UV and other space radiations which penetrated into the pores of the *R*-regolith grains and served as a source of free energy for photo- and radiochemical processes. Thin water layers around the grains did not significantly hamper the penetration of UV and corpuscular radiations. For example, a 2 cm thick layer of water is pervious to 50% of UV radiation with $\lambda = 1,880$ Å (ref. 9), while the range of UV radiation penetration in to the grains depends on the kinds of rocks and minerals and the degree of their porosity.

The conditions (1), (2) and (3) were very favourable in the *R*-regolith for various chemical reactions to take place and different radically from those existing on the unsaturated surfaces of *M*-regolith grains. Indeed, *M*-regolith grains are cleaned by solar radiation in vacuum to an 'atomically-pure' state. Therefore, only chemisorption (that is, adsorption of a monomolecular layer) can occur on their surfaces and the grains are characterised by a low adsorption capacity¹⁵. Only simple molecules can be formed on *M*-regolith grains (for example, H₂ on the Moon's regolith¹⁶).

On the other hand, distinctive characteristics of *R*-regolith grains such as a developed system of macro- and micropores and great adsorption capacity make them resemble the interstellar dust grains despite the different origin of these

properties in the latter¹⁷. Although the precise chemical composition of the interstellar dust grains is not yet known, from the results of Hoyle, Wickramasinghe¹⁷⁻¹⁹ and others, we suppose that many have a silicate matrix, and that all are covered with a polymeric mantle resulting from chemical evolution. The interstellar dust grains in this evolution played the part of a third body providing the necessary energy and momentum balances in the chemical reactions. A similar role could be played by *R*-regolith grains. All this suggests an analogy between the conditions of chemical evolution on the interstellar dust and *R*-regolith grains. Over 40 molecular compounds, including some important for prebiological evolution such as HCN, and H₂CO, have been recorded in interstellar gas-dust clouds¹⁸. In our opinion, the conditions for complex chemical reactions to occur in the *R*-regolith of the Earth were more favourable and promoted a more rapid chemical evolution than in the interstellar gas-dust clouds owing to a higher (10¹⁰–10¹² times) density of the ambient gas around the particles, significantly greater concentration of the *R*-regolith grains, relatively higher temperature ($T \approx 273$ K), and the presence of water medium. Indeed, if the grain surface is considered as a saturated gas then the rate ψ of chemical reactions, occurring on a grain surface surrounded by the ambient gas with the sticking coefficient equal to unity, will be proportional to n/t , where t is a characteristic time of the chemical reaction. At sufficiently high temperatures of the regolith grains (T_R), t can be found from the Arrhenius law: $t \sim \exp(-E_{act}/T_R)$, where E_{act} is the energy of activation ($E \leq 5$ eV) and T_R is the temperature in eV ($T_R \approx 0.04$ eV). The non-exponential dependence $t_d(T_d)$ is characteristic of the interstellar dust grains with their low temperature $T_d < 10$ K. According to Goldanski³, t_d may be constant $\approx 10^{-2}$ s, hence $\psi_R \gg \psi_d$.

These conditions could not only promote the formation of at least analogous and, apparently, even more complex compounds on the *R*-regolith but, what is more important, at considerably greater rates than on the interstellar dust grains. Moreover, the branching surfaces of the *R*-regolith grains acted as sites for the replication of complex linear molecular structures, whereas complex stereoregular structures were formed in the water medium in the pores (the conditions are described in ref. 20). For example, the surfaces of grains could accelerate the evolution of coacervates¹ which could be formed in the pores of the flooded *R*-regolith grains.

Hence, having compared the conditions in the interstellar dust and in *R*-regolith, one might confirm that the chemical evolution on the *R*-regolith could probably advance over a geologically short period to prebiological and biological forms, because of the fulfillment of conditions (1), (2) and (3). Conditions (4) and (5) were also present on the Earth at that time,

because the *R*-regolith covered the entire planet's surface uniformly and existed for a 'geological' period of time. The accumulation of an atmosphere created the conditions for the wind transfer of the *R*-regolith grains and, consequently, for the transportation of biological forms. At the same time, this atmosphere (as it accumulated and because oxidising) together with the increasing layer of water above the *R*-regolith grains could screen the action of the inhibiting factors. Note that unlike other hypotheses about the origin of life on planets our's does not indicate the existence of powerful inhibiting factors. For instance, having got into the water, a porous *R*-regolith grain could float for a certain time until most of its pores filled with water. That period of time might be sufficient for some prebiological reactions to occur in the grain whose products, together with the grain, could sink stepwise to the bottom of the pools to safely continue evolution there.

In conclusion, the conditions in the *R*-regolith during the epoch of water condensation satisfy the generally accepted conditions (1)–(6) necessary for the primary forms of life to have originated on Earth. It can also be supposed that such conditions have not been realised on Mars. The present status of the martian regolith is close to that of the Earth's *R*-regolith before the start of water condensation²¹.

Of course, the probability of finding the remains of the 'buried' *R*-regolith is extremely slim but its reproduction in laboratory conditions seems a possibility.

We thank Professors Shklovskii I.S. and Goldanskii V. I. and Drs I. L. Ettinger and Yu. B. Chernyak for stimulating discussions.

Andesitic volcanism and crustal evolution

J. C. Eichelberger

Geosciences Division, University of California, Los Alamos Scientific Laboratory, Los Alamos, New Mexico 87545

Petrological evidence indicates that andesite is a mixture of melts from the upper mantle and lower crust. Mixing is favoured by a compressional environment and generation of rhyolitic crustal melt is favoured by continental crust. Andesitic volcanism apparently involves both addition of new material to the crust and fractionation of pre-existing crust.

A CRITICAL problem in crustal evolution is whether the voluminous andesitic volcanoes and cogenetic granodioritic batholiths are derived from the mantle, crust, or both. If these

rocks originate within the crust, they represent recycled crust. If they originate within the mantle, they represent new crust. Where they occur within the ocean basins, most commonly as the andesitic island arcs of subduction zones, they represent the generation of new continental-type material in an otherwise basaltic crustal environment.

Andesite and granodiorite do not occur alone, but belong to the basalt-andesite-dacite-rhyolite association and its plutonic equivalent, the gabbro-diorite-granodiorite-granite association. Despite the enormous range in composition and physical properties of magmas represented by these rocks, field relationships demonstrate that they are intimately related in time and space. The implication of a genetic relationship among

these magmas is strong. This relationship is a key both to the origin of these magmas and of continental crust. The purpose of this article is to discuss new data on phase assemblages in volcanic rocks (Table 1) which show a remarkable similarity among a variety of igneous complexes of this magmatic association, and which point toward mixing of basaltic and rhyolitic

magmas as a dominant mechanism by which intermediate members of the association develop. The new data include representative andesites and dacites of the Cascade Range of western United States, Taupo Volcanic Zone of New Zealand, Andes of Ecuador, and Lesser Antilles (Guadeloupe and Martinique) of the French West Indies.

Phase assemblages in andesite and dacite

A particularly interesting feature of intermediate volcanic rocks is that they commonly contain phases totally out of chemical equilibrium¹⁻⁷ and of a type and composition appropriate to basaltic and rhyolitic magmas. In addition to the phenocrysts appropriate to magmas of intermediate bulk composition, andesite and dacite contain both anomalously calcic and sodic plagioclase, forsteritic olivine, and sometimes quartz. Sodic plagioclase occurs as cores of phenocrysts and is surrounded by a dark zone of skeletal calcic plagioclase with glass-bearing channels, which is in turn surrounded by a normally zoned clear overgrowth (Fig. 1). The width of the dark zone tends to be greater in phenocrysts in andesite than in dacite. Quartz phenocrysts in dacite commonly contain substantial embayments, indicating resorption. Quartz phenocrysts in andesite are commonly surrounded by glass and pyroxene jackets, indicating resorption and reaction (Fig. 2). Inclusions of rhyolitic glass occur both in the sodic cores of plagioclase phenocrysts and in quartz phenocrysts (Table 2). Forsteritic olivine and calcic plagioclase occur as individual grains and also within crystal-rich xenoliths and microxenoliths of distinctive texture and composition. Inclusions of basaltic glass within forsteritic olivine and calcic plagioclase have been reported by Anderson⁷.

The crystal-rich xenoliths range in size from clots of a few grains present in most thin sections (and individual crystal grains derived from them) to globules 1 m in diameter and are commonly referred to as 'cognate'. They are dominantly plagioclase + pyroxene + glass in andesite and plagioclase + hornblende + glass in dacite. Their texture (Fig. 3) consisting of euhedral to subhedral crystals with interstitial glass suggests advanced crystallisation of a magma. Plagioclase and hornblende in the xenoliths are strongly zoned, acicular, and often hollow, suggesting rapid growth¹⁵. Composition of the hornblende¹⁶ closely coincides with the composition of hornblende coexisting with melt in basaltic systems¹⁷ from 1,000 °C to 700 °C. Bulk composition of the xenoliths is also magmatic, falling at or near the basaltic end of the trend for the complex¹⁸ (Table 2). Those xenoliths which are intermediate rather than basaltic in composition contain sodic plagioclase and sometimes quartz, as described above. Large xenoliths are often concentrically zoned, with a coarse-grained basaltic core surrounded by a fine-grained basaltic or andesitic rind¹⁹. The textural relationship is clearly one of chilling of the xenolith against the host.

These features can be explained in the following way. The composition of the sodic plagioclase and quartz phenocrysts in andesite and dacite indicate that these phases originally grew in a rhyolitic magma. This conclusion is supported by the inclusions of rhyolitic glass within these phases. The composition of the calcic plagioclase and forsteritic olivine indicate that these phases grew in a basaltic magma. This conclusion is supported by the presence of these phases within the basaltic xenoliths and by the occurrence within these phases of inclusions of basaltic glass. This suggests that many andesites and dacites are hybrids derived by mixing of basaltic and rhyolitic magmas. Basaltic magma intrudes rhyolitic magma and breaks into globules. Mixing of liquids occurs at the interface between globules and host. The globules undergo rapid crystallisation to form crystal-rich basaltic xenoliths with andesitic rinds while crystalline phases in the cooler rhyolitic host undergo reaction or melting, forming embayments or pyroxene rims on quartz and dark resorbed zones on sodic plagioclase. These melting and reaction effects are greater in mixtures containing a higher proportion of basalt (andesite versus dacite)¹⁹. Renewed crystallisation following the mixing event results in growth of phases appropriate to the new intermediate bulk composition and temperature of the system, both as individual crystals and as overgrowths on basalt- and rhyolite-derived phases. Overgrowths protect the disequilibrium phases from further reaction. Note that the data presented in Tables 1 and 2 come from both oceanic and continental regions.

Other hypotheses have been advanced for the origin of these features in andesite and dacite. Sodic plagioclase and quartz in andesite have been attributed to assimilation of granitic rocks²⁰. These phases, calcic plagioclase, and forsteritic olivine have also been attributed to crystallisation of andesitic liquid at high pressure, dry in the case of sodic plagioclase²¹ and quartz^{22,23} and wet in the case of calcic plagioclase²⁴ and olivine²⁴. The clear, volcanic nature of sodic plagioclase and quartz (Figs 1 and 2) suggests that they are direct precipitates of magma. Further, the low ⁸⁷Sr/⁸⁶Sr of most andesite is inconsistent with significant contamination by older granitic rocks²⁵. Limited capacity of magmas to assimilate cold rocks and occurrence of andesite in island arcs lead to the same conclusion. This has caused many workers to favour the high pressure crystallisation hypothesis, but this leads to mutually exclusive conclusions concerning water content of the magma. Wet, high pressure conditions might produce the calcic plagioclase but not the sodic plagioclase. Such conditions might cause forsteritic olivine to precipitate but not quartz. It is also difficult to reconcile the high pressure hypothesis with evidence that there is isotopic as well as chemical disequilibrium between phenocryst and matrix in andesite and dacite^{26,27}. Basaltic xenoliths have been interpreted as cumulates^{9,11}, although they lack cumulate textures, and breakdown products of high Al amphiboles²⁸, although they range in size to several centimetres or even tens of centimetres. None of these alternative hypotheses seem to be consistent with the observations presented above, especially the inclusions of rhyolitic glass in sodic plagioclase and quartz and the textures of the xenoliths.

Mixing of rhyolitic and basaltic magmas provides a simple explanation for these petrological features which are both widespread and abundant in andesites and dacites. Mixing can also account for the bulk composition of these rocks, because andesitic and dacitic compositions can be approximated (with some exceptions) as a linear combination of basaltic and rhyolitic compositions^{6,19}. Therefore it seems reasonable to formulate a general model for andesitic volcanism based on this process. Although other processes may contribute to this style of volcanism, consideration of the mixing process leads to important conclusions concerning the relationship of andesitic volcanism to crustal and tectonic setting and to crustal evolution.

Sources of parental magmas

There is general agreement that basaltic magma is a product of partial melting of ultramafic material in the mantle²⁹⁻³¹. However, widespread evidence of mixing in intermediate igneous rocks suggests that the basalt-andesite-dacite-rhyolite suite is not a liquid line of descent from basalt. If rhyolite is not a product of fractional crystallisation of more mafic magmas, it must form directly from a solid source material by a melting process. Rhyolite is too siliceous to be derived by partial melting of ultramafic mantle material or even crustal material at mantle pressures³². It does, however, represent the composition of the low melting fraction of a wide variety of crustal rocks at crustal pressures³³. This suggests that rhyolite forms by partial melting in the crust, just as basalt forms by partial melting in the mantle. The lower crust, which is the hottest part of the crust, is the most probable source region.

As the lower crust is likely to be basaltic (gabbroic) or intermediate in composition³⁴, rather than granitic, rhyolitic magmas must generally form by relatively small degrees of melting of a more mafic source. Relatively low ⁸⁷Sr/⁸⁶Sr of most rhyolites also requires derivation from a mafic (low Rb/Sr) source. The rhyolite source beneath island arcs is most likely basaltic in bulk composition because oceanic crust is formed by basaltic volcanism at the mid-ocean ridges. Experimental studies show that in hydrous conditions in the lower oceanic crust,

basaltic material will be in the form of amphibolite³⁵ and that the melt will be rhyolitic in composition up to about 20% melt fraction¹⁰. Water has a critical role because it stabilises silica-poor amphibole in the presence of silica-rich liquid. The rhyolite source is probably more silicic in the case of continental crust, because silicic lavas on continents tend to be more voluminous and more radiogenic³⁶.

Widespread evidence of mixing also implies close association of basaltic and rhyolitic magmas in time and space. Field relationships attest to this close association as well. Intermediate and rhyolitic rocks are commonly localised within regions of basaltic activity^{19,37}. Hence the rhyolitic parent of these complexes forms in a region of upwards flux of basaltic magma. Because movement of basaltic magma is a most effective means of heat transfer³⁸⁻⁴⁰, it seems likely that basaltic volcanism provides heat for generation of rhyolitic magma in the lower crust and that this is the reason for the close association of basalt with rhyolite in time and space.

Formation of hybrid magmas

The presence in andesite of phenocrysts originally grown in rhyolitic magma implies that the rhyolitic liquid segregates from its source region, coalesces into a magma body, and begins to cool and crystallise before mixing. The common occurrence of granite as large stocks or plutons, the large volume of rhyolitic extrusives, and the large collapse features associated with rhyolitic volcanism indicate that rhyolitic magma moves through the crust as large blobs or diapirs. Large volumes of megascopically homogeneous hybrids suggest that mixtures are formed in large batches. Thus it seems that much of the mixing of basaltic and rhyolitic magmas involves large (often 1 km³ or more) bodies of rhyolitic magma at levels higher and cooler than the lower crust.

Megascopic homogeneity of hybrids also implies an efficient stirring mechanism, probably convection. Application of the Rayleigh-Jeffries criteria to magmas indicates that even the most viscous rhyolitic magmas should convect in most conditions of storage in the crust⁴¹⁻⁴³. Estimated rates of flow in

plutons are of the order of 1 cm s^{-1} (ref. 43), based on the experiments of Peyches and Zorzea⁴⁴ which predict reasonable rates for mantle convection. Injection of basaltic magma into an active rhyolitic pluton favours rapid and possibly turbulent convection^{39,43,45}. The system tends to homogenise itself, driven by the large temperature differences accompanying the initial heterogeneity in composition. Because convection rates are strongly dependent on size of the magma body, the stirring process is effective for pluton-sized pots but not for dispersed melt pockets in the rhyolite source region. This is consistent with the earlier observation that much of the mixing involves large batches of magma.

Field relationships shed further light on how mixing occurs. Volcanic centres which erupt intermediate and rhyolitic magmas lack basaltic vents while they are active, despite frequent basaltic activity in the surrounding region^{19,46,47}. This can be interpreted as indicating that large, active silicic magma bodies beneath these centres trap rising basaltic magma because of the lower density of the silicic magma⁴⁶. Some large volume tephra sheets from andesitic centres seem to record an early stage of mixing in which basaltic magma has been forced to sill out beneath a rhyolitic pluton⁴⁸. In the Crater Lake sheet, silicic tephra is abruptly overlain by mafic tephra. That the parent pluton was mixing, rather than differentiating, is indicated by the presence of quenched mafic material, the xenoliths described earlier, in the silicic tephra.

Statement of model

The foregoing considerations point toward a simple model for the basalt-andesite-dacite-rhyolite association (Fig. 4). Basaltic magma from the mantle rises into the crust and is emplaced at various levels as dikes and sills. In the lower crust, where the initial temperature is high, emplacement of basaltic sills causes partial melting. The resulting rhyolitic liquid gathers into plutons which rise slowly through the crust. Because the rhyolitic plutons exist in a region of upwards flux of basaltic magma, they commonly are injected with basalt and mixed by rapid convection before they crystallise or erupt. Thus basaltic volcanism causes rhyolitic magma to develop and, once formed, rhyolitic magma bodies trap rising basalt. Mixing of the two

parental magmas produces the intermediate compositions, andesite and dacite, of the association.

With this model in mind, comparison of volcanic fields of the basalt-andesite-dacite-rhyolite association in different settings suggests two important relationships: (1) generation of rhyolitic magma is favoured by continental crust and (2) mixing is favoured by a compressional tectonic environment. The first correlation was discussed above and may be due to differences in composition of the rhyolitic source. An example of how this explains variations in andesitic volcanism can be seen in the Tonga-Kermadec-New Zealand magmatic arc. Within this subduction zone, the crust of the over-riding plate varies from continental (New Zealand) to oceanic (Tonga and Kermadec). Silicic lavas of the continental portion of the arc are more voluminous, richer in K, poorer in Ca, and have higher $^{87}\text{Sr}/^{86}\text{Sr}$ values⁴⁹.

The cause of the second correlation is less clear. Extensional or rift environments, as indicated by prominent block faulting, tend to have a bimodal (basalt-rhyolite) lava distribution while intermediate compositions dominate in compressional or subduction environments⁵⁰⁻⁵². Further, changes from compression to extension in the western USA were accompanied by changes from intermediate to bimodal igneous activity^{50,51}. This suggests that extensional tectonic activity inhibits mixing, perhaps because rhyolitic plutons rise more rapidly through the crust where the crust is under tension rather than compression. Where the crustal residence time of active plutons is less, the probability of mixing is also less. Interestingly, in subduction zones, granite is more abundant among plutonic rocks than is rhyolite among volcanic rocks²⁹. Apparently there is a bias towards the eruption of mixtures. Water-rich rhyolitic plutons whose heat is not replenished by injection of basalt are more likely to crystallise at depth as granite, thereby contributing to the silicic batholiths. A further reason for the bias towards eruption of mixtures is that mixing at shallow levels can trigger eruptions by causing vapour exsolution in the magma^{43,45}.

These environmental parameters, continental or oceanic crust, compressional or extensional tectonics result in four categories which determine major characteristics of silicic igneous activity. Continental crust and compressional tectonics

Fig. 4 Model for genesis of the basalt-andesite-dacite-rhyolite association, applied to subduction and rift zone volcanism. In both cases, melting in the mantle gives rise to basaltic magma and melting in the lower crust yields rhyolitic magma. In subduction zones, intermediate lavas predominate at the surface due to mixing of basaltic and rhyolitic magmas within plutons in the mid to upper crust. In rift zones, an extensional environment permits rapid rise of rhyolitic plutons. Both basaltic and rhyolitic magmas reach the surface with little mixing. Except for differences in amount of mixing, the two cases represent a similar response of the crust to heat from the mantle. The rhyolitic component involved in volcanism is larger if the crust is more continental in character.

Table 2 Some observed and inferred compositions of continental margin and island arc parental magmas

result in a large rhyolitic component and substantial mixing. The Andes Mountains and Taupo Volcanic Zone are examples. Continental crust and extensional tectonics result in a large rhyolitic component and little mixing. The Yellowstone Plateau and East African Rift are examples. Oceanic crust and extensional tectonics result in a small rhyolitic component and little mixing. Iceland and Easter Island are examples. Finally, oceanic crust and compressional tectonics produce a small rhyolitic component and substantial mixing. Tonga and the Lesser Antilles are examples.

Evolution of the crust

In the model discussed here, andesitic volcanism involves both addition to the crust of new material from the mantle and fractionation of pre-existing crust. With time, these processes of thickening and fractionation would result in evolution from oceanic crust, thin and basaltic, to continental crust, thick and enriched in the low-melting component in its upper portion.

Andesitic island arcs, where thickened oceanic crust is trapped over a heat source, appear to represent an early stage in this evolution. Critical factors which determine whether crustal melting, and hence crustal fractionation, occurs are thickness of the crust, the presence of water, and heat transport from the mantle, either by conduction alone or augmented by movement of magma. Mixing is simply a consequence of crustal melting induced by intrusion of basaltic magma. The higher the conductive heat flow from the mantle the greater the crustal melting accompanying basaltic volcanism. Hence this process of crustal fractionation may have been more efficient earlier in the Earth's history than it is in modern island arcs.

Discussion

This view of andesitic volcanism is a departure from some current thinking on volcanic rocks, but closely resembles models for batholiths^{29,39,53,54}. As such it provides a consistent explanation for the origin of both the volcanic rocks and their

batholithic equivalents. The similarity of these volcanic and batholithic rocks extends beyond bulk composition to many of the petrological features discussed here¹⁶.

Test of optimal sampling by foraging great tits

John R. Krebs

Peter Taylor

Department of Mathematics, Queens University, Kingston, Ontario, Canada

When great tits forage in an unknown environment containing two feeding places of different profitability, they first sample the two places and then exploit the more profitable one. The balance between sampling and exploitation shown by the birds is close to an optimal solution for maximising the number of food-items obtained during a feeding period.

OPTIMAL foraging models, based on the premise that animals collect food in a way which maximises their net rate of food intake, have been quite successful in predicting the decision rules used by predators in laboratory experiments¹⁻⁹, but so far, little work has been done on the problem of how a predator samples the environment. Sampling is an implicit necessity of optimal foraging models, which assume that the predator behaves as if it knows the availability of different prey types or patches of food. We describe here an experiment designed to test whether or not the great tit, *Parus major*, uses a maximally efficient set of rules when sampling a patchy environment.

Two possible methods of obtaining maximal food intake with a choice of foraging area

Our experimental set up is extremely simple. The naïve bird is faced with a choice of two foraging places (patches) which differ

in availability of food. The availabilities remain constant throughout a particular experiment, and the bird can only discover by exploration which of the two patches is better. On the other hand, the bird has distinguished between the quality of the two patches, it should concentrate on exploiting the better one; however, in our experiment we are concerned with how the bird makes the decision about which patch to exploit. We suggest that there are two simple types of maximising rules. On the one hand, the predator might attempt to maximise its rate of intake at every instant in time by always foraging in the patch with the higher expected reward rate. We refer to this strategy as 'immediate maximising'. Alternatively, the predator might attempt to maximise its intake over the total foraging time by sacrificing short-term gain in order to acquire more information about the relative quality of the two patches. In this second strategy, an efficient predator has to choose the appropriate balance between exploration and exploitation. Our main aim is to test whether or not great tits follow this strategy and if so, whether they approximate an optimal balance between exploring and exploiting. The advantage of the sample-then-exploit strategy is that, in contrast to the strategy of immediate maximising, there is no risk of choosing the less profitable patch.

Solution of the 'two-armed bandit' problem
The problem of choosing the optimal balance between exploration and exploitation is similar to the classical 'two-armed bandit' problem, in which the player is faced with two

Fig. 1 'Two-armed bandit' simulation.

lines, each with a characteristic, unknown reward rate on a random schedule, and the goal is to maximise the expected number of rewards in N trials^{10,11}. This problem can be solved by a dynamic programming algorithm which works backwards from the N th trial, at which point the machine with the higher percentage rewards is chosen. The algorithm involves analysing each stage, n , the payoff for two possibilities (exploit or exploring) in terms of the known optimal behaviour at stage $n + 1$.

Our model is a modification of the optimal solution of the two-armed bandit problem¹². We consider that the bird has a total of N trials (the meaning of which will become apparent), and at the beginning of an experimental session it goes to each patch alternately. After M trials in each patch it commits itself to one patch or the other, so that all strategies take the form: M trials in each patch (exploration) followed by $N - M$ trials on one patch (exploitation). In our model we added the constraint of equal sampling effort in the two patches during exploration, because this simplifies the model without significantly altering its predictions. The model predicts that

value of M , the point at which the predator decides to exploit, changes with p_1 and p_2 , the reward probabilities in the two patches. Intuitively, one would expect M to decrease as $|p_1 - p_2|$ becomes larger, and our model predicts the exact shape of the curve.

The details of our algorithm, which uses a Bayesian approach to describe the information possessed by the bird at each stage, are as follows. At the start of the experiment, the birds' prior estimate of p (the parameter of the Bernoulli process which is the reward rate in a patch) is considered to be β -distributed with parameters (α, β) , and therefore, with mean $(\alpha + 1)/(\alpha + \beta + 2)$ and variance $(\alpha + 1)(\beta + 1)/(\alpha + \beta + 2)^2(\alpha + \beta + 3)$. The distribution has the property that after n trials with r successes, the posterior estimate of p is also β -distributed with new parameters $(\alpha + r, \beta + n - r)$. Thus, it is easy to follow the state of the bird's information about the two patches by updating α and β after each trial. In simulating the model, we used starting values of $\alpha = 0, \beta = 0$ for both patches. This means that the bird's initial estimate of the mean reward probability in the two patches is 0.50 with a uniform distribution between 0 and 1.0. Thus, after n

trials with a_i successes, the bird's revised estimate of the reward rate p in patch i is $(a_i + 1)/(n + 2)$. We investigated the effect of varying the prior, by calculating our predictions for the following values of α and β : $\alpha = 0, \beta = 2$; $\alpha = 0, \beta = 0$; and $\alpha = 2, \beta = 0$. The model was rather insensitive to changes in the prior, most of the changes in prediction being between 10% and 20%.

If, after n trials in each patch, the bird decides to sample once more, its expected payoff for the remainder of the foraging time is E_s , whereas if it decides to exploit, its payoff is E_D . The optimal strategy is to choose the larger (E) of these two values. E_s can be calculated in terms of the values of E at stage $n + 1$ as follows:

Let

$$\pi_i = (a_i + 1)/(n + 2)$$

Then

$$\begin{aligned} E_s(a_1, a_2, n) = & \pi_1 + \pi_2 + \pi_2 \pi_1 E(a_1 + 1, a_2 + 1, n + 1) \\ & + \pi_1(1 - \pi_2)E(a_1 + 1, a_2, n + 1) \\ & + (1 - \pi_1)\pi_2 E(a_1, a_2 + 1, n + 1) \\ & + (1 - \pi_1)(1 - \pi_2)E(a_1, a_2, n + 1) \end{aligned}$$

and

$$E_D(a_1, a_2, n) = (N - 2n) \max \{ \pi_1, \pi_2 \}$$

Figure 1 gives further details.

The model is simulated by starting with $2n = N$ and working backwards, generating E_s , E_D and E recursively. At each stage, the model produces an $n \times n$ matrix giving the value of $(E_D - E_s)$ for each combination of values of a_1 and a_2 . When the bird is at the last pair of trials, E_D is clearly higher than E_s , assuming there is a difference in the two reward probabilities. As the simulation works backwards, it becomes more likely that, for any particular combination of a_1 and a_2 , the payoff for sampling once more in each patch (and hence acquiring more information about the profitability of the two patches) is higher than the payoff for deciding to exploit. The exact point at which this change from sampling to decision occurs depends on the value of the total number of trials N , which in effect represents the bird's time horizon. For given values of a_1 and a_2 , the larger the value of N , the longer the bird should sample before deciding. We ran the model with a range of values of N .

The experiment

In our experiments, the two patches consisted of two identical operant feeding places at opposite ends of an indoor aviary (measuring 4.3×3.7 m). The feeding places consisted of a perspex disk 35.5 cm in diameter enclosed in a shallow metal box measuring $38.5 \times 38.5 \times 9$ cm. The disk was drilled with 72 holes (diameter 0.7 cm, depth 0.4 cm) around the perimeter of its upper surface. Each of these holes contained a piece of mealworm (weight 0.07 g), and the bird had access to one hole at a time through a small horizontal window in the top of the box which enclosed the disk. To get at the next piece of food, the bird hopped on a perch next to the disk, which operated a solenoid-driven stepping cog to turn the disk through a small angle, bringing the next hole into line with the window. The reward rate was set on a pseudo-random variable ratio schedule using BRD modular logic units. This experimental set up is exactly analogous to that used in probability learning experiments¹³.

The experiments were carried out between June 1976 and February 1977 and involved testing nine wild-caught, adult great tits. Each bird was first trained to perform the operant task and then given a series of tests of different treatments consisting of various percentage reward rates in the two disks. The values we used were 50:0; 40:10; 35:15; 30:20. It is important that although these ratios always summed to 50%, we think the birds did not learn this, as between each treatment they were subjected to a series of one to four 'neutralisation' tests in which both disks offered a 7.5% reward rate. These tests were always continued until the bird showed no marked preference for one

disk over the other; we used a low reward rate during neutralisation sessions because we found this to be effective. If there was a slight preference, the less preferred disk was used as the more profitable place in the next treatment. A 'treatment' (for example, 20:30) consisted of a series of between 1 and 5 10-min tests. We had to run a series of short tests because the birds sometimes emptied one of the disks of rewards before a treatment was completed. When this happened, we interrupted the treatment for a short time while the disk was refilled. During these interruptions the bird was locked outside the test aviary without food, and in our analysis we always discounted the first 20 hops after an interruption. Any particular treatment was continued until the bird had 'decided' to exploit one disk or the other (nearly always the more profitable place).

The decision criterion was that the bird should perform more than 90% of a sequence of 100 hops on the preferred perch. This decision criterion was chosen after calculating the probability of the bird going back to the less profitable perch for a bout of 20 or more hops after different lengths of hopping bouts on the profitable perch. With the 100-hop criterion the probability of this type of reversal is nearly asymptotic and is less than 5%. Each bird was tested twice with all five treatments, the sequence of testing being randomly chosen. At the beginning of each treatment, the test bird was deprived of its normal food and excluded from the indoor aviary while the disks were being loaded with prey. Preliminary trials showed that the birds worked at a constant rate (15 hops per min) throughout a series of tests after an initial 60-min deprivation, which was the minimum period we used. The data were recorded on a computer-compatible event recorder which stored the information on magnetic tape.

Fig. 2 *a*, The predicted (—, ---) and observed (●) number of hops before making a decision (nine birds). Three predicted curves based on the 'sample-then-exploit' model are shown, for $N = 50, 150$ and 250 . The observed means are close to 150 (continuous line) curve. Also shown are the 95% confidence intervals of the observed geometric means (we used geometric means to normalise the distribution). The x axis is the difference in reward probability between the two perches for the five experiments (for example, 50:0, difference = 50; 35:15, difference = 20). *b*, A frequency distribution of lengths of tests. The modal value is close to $N = 150$, which gave the best fit in Fig. 3*a*. $\bar{x} = 199$.

Fig. 3 The observed number of 'giving-up hops' (unsuccessful hops before a departure) plotted against reward probability. The random curve is calculated taking into account the fact that the birds tend to hop in short bouts. If p is the probability of getting a reward on a single hop and $q = (1 - p)$, then the expected number of giving up hops for bouts of $5 = qp + 2q^2p + 3q^3p + 4q^4p + 5q^5p$. The observed points lie very slightly, but consistently above the random departure line, indicating that the birds tend to leave a perch after a run of bad luck. The observed points are $\pm$ standard error.

Treatment of results

The results of these experiments showed that the birds followed the general pattern of behaviour assumed by our version of the two-armed bandit model. There was an initial sampling period during which the birds performed on average 42% of hops on the more profitable and 58% on the less profitable perch. This proportion does not differ significantly from 50:50, and is consistent with the constraint of equal sampling in our model. The slight bias towards the less profitable perch resulted from our experimental procedure of always starting with the higher reward rate in whichever perch was used less in the preceding neutralisation test. After the decision point, the birds spent virtually all their time on the more profitable perch; on average, 95% of hops were on this perch, and the range for individual treatment means was 88–99%. Similar results, referred to as 'maximising' on concurrent variable ratio schedules, have been obtained with pigeons¹³.

In terms of our optimal decision model, we can consider a hop as being equivalent to a single trial, so that we can predict, for each combination of reward rates, how many hops on each perch the bird should do before making the decision to exploit. Figure 2a shows the observed mean decision point in each experimental treatment and the predictions of the model for three values of N (total number of hops in the experiment), 250, 150 and 50. The fit to the model with $N = 150$ is good; not only is the observed curve the same shape as predicted, but the predicted values are all fairly close to the observed means. The other values of N give curves of the same general shape, but with predicted values too high or too low. The value of N which fits the data (150) is the modal value for the number of hops performed in a test (Fig. 1b). This suggests that birds are optimising over the 'time horizon' which they experienced most often during our experiments, but we do not know if the birds would optimise with a bigger value of N if they were accustomed to longer tests. We plan to test this possibility. There is a slight difference in the modal value of test lengths for different treatments, but as the treatments were presented in a random order there is no reason to suspect that the birds could modify their behaviour according to treatment.

One way in which the birds' behaviour differed from that implied in our model is that they did not sample by doing one hop on each perch at a time, but instead they hopped in bouts of about five. (The overall mean bout length before decision was

5.00, the range 3.00–16.5.) This makes no difference in predicting the average decision point, but if the birds had hopped in rigidly determined bouts, the predicted decision point for a particular experiment would have to be a multiple of 5, which would involve reading every fifth matrix of the model's output. This tendency to hop in bouts probably explains why the observed points are above those predicted at the right-hand end of the graph where the bird should make a decision after about 10 hops.

The alternative goal we considered above was the strategy of immediate maximising, in which the bird always switches to the perch with the higher current expected reward rate. We used the β -distribution and the same starting values of α and β as above to predict, for any given experiment, at which point the birds should no longer switch back and forth if they were following this strategy. This predicted point is reached when expected payoff in the current patch never drops below that expected in the other one. The observed point was based on the decision criterion discussed above. The expected number of switches depends on the actual sequence of obtaining rewards in the first few moments of the experiment. In calculating the expected values we made the conservative assumption that the birds would continue to switch until the difference between patches in expected reward rate was greater than 5%. The observed mean values for the five treatments (50:5, 45:5, 40:10, 35:15, 30:20) were 3.3, 3.6, 3.8, 6.4 and 9.6, whereas the corresponding expected values were 0.93, 1.3, 1.36, 1.3 and 3.25. If we relax the assumption that the birds cannot discriminate differences of less than 5% in our experiments, the difference between observed and predicted values becomes even greater. Clearly, the birds switch more than expected. In other words, they are not maximising in the very short term, but instead they behave as if they acquire information to achieve a longer-term optimum.

Although the birds do not seem to switch according to the rule of immediate maximising, there is some evidence that switches between perches are related to short-term changes in reward rate. In Fig. 3 we plot the number of unsuccessful hops before a switch during the sampling period as a function of reward rate. The points lie very close to, but slightly above, the random departure curve. This random curve takes into account the fact that the birds work in bouts rather than single hops. Eight out of 10 means lie just above the random curve ($P \approx 0.05$). This shows that birds have a slight tendency to switch after a run of bad luck. In other words, they have a weak component of immediate maximising in their sampling strategy.

Discussion

The bird's behaviour approximates the prediction of a simple model based on a constrained optimal balance between exploration and exploitation, and does not fit the model of pure exploitation. The fit to the former model is close in spite of the fact that we have not yet directly incorporated a cost of switching between patches. In effect, we incorporated a small cost by using the rule that if the payoffs for sampling and exploiting were exactly equal, then the bird should exploit. In our experiment, this cost was small both in energetic terms and in time. However, in further developments of the model the cost of switching might be an important consideration.

Our comparison of the two maximising models has been in terms of predicting the details of the bird's behaviour, but an alternative approach is to compare the payoff, measured as number of rewards per test. On average, the two-armed bandit model achieves a slightly higher payoff than immediate maximising, except in very short experiments with less than five trials¹⁴, but when the reward rates are very different in the two patches (for example, 50:0) and the risk of a wrong decision is negligible, immediate maximising is just as effective. The difference between the birds' behaviour and that predicted by the two-armed bandit model, although small, is sufficient for the birds to do slightly worse than either of the two models in terms of payoff. However, the difference is less than 5% of the

predicted optimum of the two-armed bandit model (A.K. and J.K., in preparation). Thus, an analysis of payoffs enables us to say that the birds are close to the optimum but does not discriminate between the two models, unlike the analysis of the birds' behaviour.

We have presented averaged data for the nine birds we tested, but individual variation was very marked. We considered the possibility that some individuals are more cautious (do more exploring) but are less likely to make mistakes. Five of the nine individuals tested made one or more mistakes (that is, chose the poorer patch) in the 30:20 or 35:15 tests. These individuals did not make decisions after fewer hops than the other four birds. The average number of hops before a decision for all treatments was 23.9 ± 9.6 and 18.4 ± 9.8 for the fallible and infallible individuals, respectively. If, however, we examine individual treatments in which a bird made an incorrect decision, it is apparent that these tend to be cases in which the bird did little or no sampling. Examining the 18:20:30 treatments (nine birds, two treatments each), only three out of the 13 in which a correct decision was made involved no sampling, whereas two out of the five in which the bird made a mistake were tests in which there was no sampling period at the beginning.

Although the birds in our experiments behaved on average as if they were calculating an optimal balance between exploration and exploitation, we suggest that they use some simple rule to

approximate the optimum. We have simulated various potential rules including 'matching' future responses to rewards obtained so far, an empirically derived rule applying concurrent choice experiments¹⁵. The extent to which these proximate rules mimic the behaviour of the birds and match the total payoff achieved will be discussed elsewhere (A.K. and J.K., in preparation).

We thank the SRC for financial support, Mike Cullen and John Gittins for valuable advice, and Nick Styles, Janet Lomer and Ruth Ashcroft for help with the experiments. Ted Fleming and Nick Davies commented on the manuscript.

Electrophoretic movement and localisation of acetylcholine receptors in the embryonic muscle cell membrane

Norman Orida & Mu-ming Poo

Department of Physiology, California College of Medicine, University of California, Irvine, California 92717

A steady electric field of 30 mV across a single embryonic muscle cell produces accumulation of acetylcholine receptors toward one pole of the cell within 1 h. The movement is electrophoretic in nature and the accumulation results in the formation of stable, metabolically independent receptor aggregates.

MANY cell membranes are fluid in structure¹, and proteins and lipids are free to undergo long-range movement in the plane of the membrane²⁻⁵. Under many circumstances, however, mobile membrane components may be localised and concentrated at specific regions of the cell membrane. The mechanism that modifies and stabilises their topographic distribution in the fluid matrix is poorly understood. One notable example is the acetylcholine (ACh) receptors at the neuromuscular junction. Embryonic muscle membrane before innervation is covered by ACh over the entire surface of the muscle^{6,7}. After innervation, the ACh sensitive site is essentially confined to the junctional region of the muscle membrane^{6,8,9}. Since muscle cell membranes are fluid^{10,11}, and redistribution of receptors during the course of innervation has been demonstrated^{12,13}. We present here our study of the induced movement and localisation of the ACh receptors in muscle cell membranes. We found that when a steady electric field of 10 V cm^{-1} (corresponding to a potential of 30 mV across a cell $30 \mu\text{m}$ in diameter) was applied to the surface of spherical *Xenopus* muscle cells, the receptors rapidly accumulated towards one pole of the cell. This accumulation of receptors is consistent with the electrophoretic redistribution of mobile, charged receptors in the plane of the cell membrane. The redistribution is independent of metabolic energy, blocked by the preincubation of the cells with concanavalin A (Con A) and reversed in direction after surface charge modification with neuraminidase. Moreover, the formation of the ACh receptors leads to the immediate formation of stable receptor aggregates which persist against diffusion, resist treatment with cytoskeletal disrupting agents and require no metabolic energy supply for their stability.

Electrophoretic mapping of ACh receptors

Single embryonic muscle cells, obtained by dissociating neurones of *Xenopus laevis* embryos (stage 18-19, ref. 1) were used as a monolayer on clean glass culture chambers and re-used for experiments after 2.5-3.5 d in culture. Culture medium contained 85% Steinberg's saline¹⁵ (58 mM NaCl, 0.0% Leibovitz medium (L-15, Gibco), and 5% fetal calf serum (Gibco). Within 2.5 d of culture, embryonic muscle cells of two distinct morphologies were observed, extended and rounded. All experiments were carried out on the extended mononuclear cells (diameter $35 \pm 5 \mu\text{m}$) that adhered tightly to the culture substratum (Fig. 1a). Details of the methods and apparatus have been reported elsewhere¹¹. Briefly, an electric current was applied to the thin, rectangular culture chamber of defined geometry ($6.0 \times 1.0 \times 0.2 \text{ cm}$) containing culture medium. A current of 1.5 mA

averaged $6.3 \pm 1.0 \text{ V nC}^{-1}$ (row 2, Table 1). Figure 1c shows representative asymmetrical responses of a cell after 1.5 h exposure to the field, and Fig. 2 plots peak depolarisation against charge ejected through the ACh pipette for two cells from the same culture. The sensitivities on the two poles of these cells were mapped before (cell a) and after (cell b) exposure to the field for 1.5 h. For the cell exposed to the field, the slope of the curve increased at the cathodal pole, and decreased at the anodal pole. In several experiments, we also mapped the sensitivity along the perimeter of the cell from 0° to 180° . It was consistently found that the positions with increased sensitivity were always centred around the 0° pole, whereas the sensitivities of all other positions decreased slightly from the control level. Figure 3 shows perimeter mappings for a control cell and three cells from three separate cultures exposed to the standard 10 V cm^{-1} field for 45 min, 1.5 h and 3 h, respectively.

To evaluate the degree of asymmetry in ACh sensitivity induced by the electric field, we defined an asymmetry index with the formula described in Table 1. This formula gives an index of 0 for a cell showing equal sensitivities on the cathodal and anodal pole of the cell, an index of 1 when the sensitivity is entirely confined to the cathodal pole, and an index of 0.5 when the sensitivity is threefold higher at 0° than that at 180° . By plotting mapping data for a series of cultures exposed to different durations of the same field, we found that the redistribution of ACh sensitivity reached a plateau asymmetry index of about 0.5 (Fig. 4).

Fig. 2 Dose-response curve of the muscle cell membrane to applied ACh. Curves were obtained by plotting peak depolarisation produced by the picocoulombs of charge ejected from the ACh pipette. Slopes of lines drawn by eye were used as a measurement of sensitivity. Cells a and b were from the same culture and were mapped with the same ACh pipette before (a) and after (b) exposure to a field of 10 V cm^{-1} for 1.5 h. Sensitivities at 0° and 180° were 9.3 and 8.8 V nC^{-1} , respectively, for cell a, and in contrast, 14.5 and 4.3 V nC^{-1} , respectively for cell b. E_m during mapping ranged between -100 to -104 and -94 to -98 mV for a and b, respectively.

The asymmetric redistribution of ACh sensitivity was not due to the redistribution of acetylcholinesterase, the hydrolysing enzyme for ACh, over the cell surface. When iontophoretic mapping was carried out using a pipette filled with 3 M carbachol (Sigma), a non-hydrolysable ACh analogue, similar asymmetrical redistribution of sensitivity was found (row 4, Table 1). It is interesting, however that the absolute sensitivity of these cells towards carbachol is about fivefold lower than that towards ACh in identical iontophoretic conditions.

The redistribution of ACh sensitivity was a process independent of cell metabolism. In three separate experiments, cultures were preincubated in saline containing 10^{-2} M sodium azide, 10^{-3} M dinitrophenol and 10^{-3} M sodium fluoride for 45 min. This treatment blocks the contraction response of these muscle cells to bath-applied ACh (1 mM), indicating a

Fig. 3 Mapping of ACh sensitivity at various points along the perimeter of spherical muscle cells (inset). Four cells from four different cultures were exposed to a field of 10 V cm^{-1} for 0 min (●), 45 min (○), 1.5 h (◇) and 3 h (□). Arrow indicated direction of field.

depletion of metabolic energy. Cells so treated were then exposed to the standard field for 1.5 h, still in the presence of the metabolic inhibitors. Post-field mapping indicated that although the absolute sensitivities decreased on both sides of the cells (due to progressive loss of the membrane potentials), similar redistribution of ACh sensitivity still occurred (compare rows 2 and 5, Table 1). Consistent with the finding that the observed redistribution is a passive process driven by the external field, we found that cytoskeletal elements do not seem to be involved in the redistribution process. Preincubation of the cultures in saline containing cytochalasin B (Sigma, $10 \mu\text{g ml}^{-1}$) and colchicine (Sigma, $20 \mu\text{M}$) for 1 h does not affect the redistribution of ACh sensitivity subsequently induced by the field (row 6, Table 1). Such treatment is known to block active capping processes of surface receptors in other cell types²⁰.

The effect of Con A and neuraminidase

The above observations indicated that the redistribution of ACh sensitivity is consistent with a passive electrophoretic redistribution of ACh receptors in the plane of the cell membrane. If there was indeed a redistribution of the pre-existing ACh receptors, immobilisation of ACh receptors

Fig. 4 Rise of asymmetry index with increased duration in an electric field (10 V cm^{-1}). Data were from many experiments grouped for mappings done within 4 h of removal from field. Error bars represent 95% confidence levels. The figures indicate the number of cells mapped for each duration. Data with dashed error bars indicate cultures which were preincubated with Con A for 10 min before the field was applied.

Table 1 Redistribution of ACh sensitivity induced by electric field

Duration of field exposure (10 V cm ⁻¹)	No. of cells mapped*	ACh sensitivity† (V nC ⁻¹)		Asymmetry index‡
		At 0° (cathodal pole)	At 180° (anodal pole)	
1. C (no treatment)	7 (11)	9.45 ± 0.65	9.44 ± 0.63	0.01 ± 0.02
2. 1.5 h	4 (5)	18.9 ± 2.3	6.3 ± 1.0	0.48 ± 0.04
3. 30 min	18 (3)	18.4 ± 3.8	9.1 ± 1.5	0.33 ± 0.07
4. 1.5 h (carbachol pipette)	17 (1)	4.0 ± 0.9	1.3 ± 0.4	0.49 ± 0.08
5. 1.5 h (metabolic inhibition)	14 (3)	15.6 ± 5.0	6.4 ± 1.5	0.37 ± 0.11
6. 1.5 h (treatment with cytochalasin B and colchicine)	15 (1)	10.6 ± 2.0	4.2 ± 0.6	0.42 ± 0.06
7. 1.5 h (preincubation with Con A)	19 (2)	7.3 ± 1.4	7.9 ± 1.2	-0.04 ± 0.08
8. 1.5 h (preincubation with neuraminidase)	22 (3)	6.5 ± 1.5	14.1 ± 2.4	-0.37 ± 0.08

*All isolated spherical cells mapped successfully (membrane potential $|E_m| \geq -80$ mV, $\Delta E_m \leq 10$ mV during mapping) were included. Data were pooled from separate cultures (number of cultures shown in parentheses). As there was no relaxation of the asymmetry after the removal of field (see last section and Fig. 5), data were pooled regardless of the exact time the mapping was carried out.

†Sensitivity presented as (average) ± 95% c.l.

‡Asymmetry index = Sensitivity at 0° - Sensitivity at 180° / Sensitivity at 0° + Sensitivity at 180°, was calculated for each cell before averaging, and presented as (average) ± 95% c.l.

before the application of the field should prevent the redistribution of ACh sensitivity. The following experiments using Con A provide such a control. Con A is a tetravalent lectin molecule that specifically binds to the α -D-mannose or α -D-glucose residues of cell surface glycoproteins and glycolipids², and is known to crosslink and immobilise surface receptors². In control cultures not exposed to the field, incubation with Con A (Sigma, grade III, 150 μ g ml⁻¹) for 10 min did not greatly affect the absolute ACh sensitivity of the muscle cells. The distribution of ACh sensitivity was essentially uniform along the whole perimeter of the cells. For the cells preincubated with Con A then exposed to the standard field for various times, no significant asymmetry in the sensitivity was produced at the 0° and 180° poles (Fig. 4, open circles, and row 7, Table 1). We have shown previously¹¹ that preincubation with Con A blocks the electrophoretic accumulation of the Con A receptors, as indicated by post-field fluorescent Con A ring staining. As the ACh receptor is probably a subset of Con A receptors²², the present finding is consistent with the idea that immobilisation through Con A binding prevents electrophoretic movement of the ACh receptors.

Fig. 5 Stability of asymmetrical ACh sensitivity after removal from the electric field. Data from 10 separate cultures were grouped into 90-min bins and averaged for cells exposed to the field for 1.5 h without further pharmacological treatment (●—●). Data were grouped into 30-min bins and averaged for cells either exposed to the field for 1.5 h, and then treated with sodium azide and DNP (at arrow) for the remainder of the experiment (○—○) or treated with cytochalasin B and colchicine (□—□) during the entire experiment (1 h preincubation, 1.5 h field, and post-field mapping). Each data point, on average, represents seven independent measurements. For clarity, error bars (±95% c.l.) are included only for the 90-min bins.

The surprising effect of neuraminidase treatment on the redistribution of ACh sensitivity provided additional evidence that the redistribution is electrophoretic in nature. Neuraminidase removes sialic acid from the cell surface, reducing the negative charges on membrane constituents²³. We preincubated our culture with neuraminidase (Sigma, grade VI, 0.1 unit ml⁻¹) for 1 h at pH 6.6. The enzyme-containing saline was then substituted with culture medium and the field of 10 V cm⁻¹ was applied. Post-field mapping showed that the redistribution of ACh sensitivity reversed its polarity for all cells mapped (22 cells in three separate experiments; row 8, Table 1), as compared to cells not treated with neuraminidase. The sensitivity at the anodal pole increased greatly whereas that at the cathodal pole decreased. The reversal in the direction of redistribution is probably due to the modification of charged groups on the cell surface by the enzyme. The fact that ACh sensitivity increased on the cathodal side of the cells not treated with neuraminidase suggests that ACh receptors are positively or less negatively charged than other mobile membrane components. It is likely that ACh receptors are, in fact, negatively charged but contain fewer sialic acid moieties than other more negatively charged components. After neuraminidase treatment, they become among the most negatively charged components, and hence, accumulate at the anodal pole. It should be noted, however, that a full understanding of the electrophoretic redistribution of various membrane components still requires more information on the interaction between the charged groups on the cell surface and on the effect of various counter-ions on the charged moieties.

Stability of receptor aggregates

An interesting finding in the present study is that field-induced asymmetrical ACh sensitivity always persists after removal of the field. Figure 5 shows the asymmetry indices for cells mapped at various times after removal from a 1.5 h standard field. Previously¹¹, it was shown that field-induced accumulation of the most mobile population of Con A receptors in these muscle cells undergoes relaxation after removal from the field. Rapid back diffusion results in the recovery of uniform distribution within 30 min. In our present study, for cultures exposed to a field of 10 V cm⁻¹ for 1.5 h, the asymmetry indices persisted for as long as the mapping was carried out (up to 5 h). The stability of the field-induced receptor aggregates is not dependent on cell metabolism. Figure 5 (open circles) shows a series of mapping data obtained from cultures exposed to the field for 1.5 h, but in which the regular saline was replaced (at arrow) with saline containing metabolic inhibitors (10⁻² M sodium azide, 10⁻³ M dinitrophenol). For as long as the cells remained viable under this treatment, we found no significant change in the stability of the asymmetry. Drugs disrupting cytoskeletal structure also produced no effect on the stability.

Asymmetry persisted for up to 4 h in the presence of $10 \mu\text{g ml}^{-1}$ of cytochalasin B and $20 \mu\text{M}$ of colchicine in the saline (Fig. 5, open squares).

Although stable against back diffusion, the field-induced ACh receptor aggregates were still electrophoretically mobile. When a field of the same strength, but different polarity was applied to a culture previously exposed to the standard field, a second accumulation of the ACh receptors occurred at the new cathodal poles of the cells. The sensitivity at the original cathodal pole declined to the control level (unpublished data). Our observations on the accumulation of ACh receptors by the field, the stability of aggregates against back diffusion and their mobility under subsequently imposed fields of different polarity have now all been confirmed using fluorescently labelled α -bungarotoxin²⁴, a venom protein known to bind specifically to ACh receptors.

In conclusion, we have demonstrated the electrophoretic movement and localisation of a specific membrane protein/ionic channel in the plane of the cell membrane. The technique of *in situ* electrophoresis reported here may prove useful in perturbing the receptor topography on the cell surface and in dissecting the dynamics of receptor interactions. Whether endogenous electric fields within developing tissue are involved in the localisation of cell surface receptors remains to be elucidated.

letters to nature

Origin of pregalactic microwave background

THE photon density in the observed thermal (~ 2.7 K) microwave background is $n_{\gamma 0} \approx 400 \text{ cm}^{-3}$. This contrasts with the present mean baryon density in the Universe, n_{b0} , which is in the range 10^{-5} – 10^{-6} cm^{-3} . In the standard 'hot big bang' cosmology, the ratio n_{γ}/n_b is essentially constant during the expansion, its value being

$$\mathcal{S} = n_{\gamma}/n_b \approx 3.6 \times 10^7 (\Omega h^2)^{-1}. \quad (1)$$

h denotes the Hubble constant H_0 in units of $100 \text{ km s}^{-1} \text{ Mpc}^{-1}$, and $\Omega = \frac{8\pi}{3} G \rho H_0^{-2}$ is the usual density parameter. $\mathcal{S}$ is an undetermined free parameter of the 'primordial fireball': the standard 'hot big bang' theory as yet gives no reason that $\mathcal{S}$ should be $\sim 10^8$ rather than (say) $\sim 10^4$ or $\sim 10^{12}$. Its observed value could be more readily understood in a different theory that attributes the radiative energy and entropy production to calculable processes in a specified epoch. There have been various proposals along these lines¹⁻⁹, but none has found as much favour as the standard 'hot big bang' cosmology. This is because production of the radiation at a redshift z requires a mass-energy conversion efficiency of the order

$$\rho_{\gamma}/\rho_b \approx 2.5 \times 10^{-5} (1+z)(\Omega h^2)^{-1} \quad (2)$$

This is implausibly high if z is large enough ($\gg 10^3$) to permit thermalisation by H and He plasma alone⁷⁻⁹; on the other hand, if z corresponds to the epoch of galaxy formation (or later), adequate thermalisation at centimetre wavelengths requires implausibly efficient opacity³⁻⁵. Here a possible non-primordial origin of the microwave background is outlined that seems less contrived than other such schemes.

For reasons outlined below, the dominant form of mass in the present Universe could be 'dead' remnants of massive or supermassive stars that formed when $t \leq 10^6$ yr. The active bright phase of these objects would last $\leq 10^7$ yr (and would be

over long before galaxies assembled as identifiable units) but could have generated enough radiation to satisfy equation (2) at $z \geq 100$. The uncondensed gas could, even at this early epoch, have been contaminated by the products of nucleosynthesis: it could contain heavy elements, molecules and dust, and would be dense and opaque enough to thermalise this radiation at a few hundred degrees, yielding a present-day microwave background with the characteristics observed.

To motivate a fuller astrophysical discussion of the radiation production and thermalisation, a general argument is outlined first which shows why this type of model naturally 'predicts' a value for $\mathcal{S}$ of order 10^8 .

Associated with any luminous gravitating objects where electron-scattering provides the dominant opacity is a critical luminosity, the 'Eddington luminosity' L_E , for which radiation pressure balances gravity. A characteristic timescale for conversion of rest mass into radiation is then¹⁰

$$\frac{Mc^2}{L_E} = t_* = \frac{c\sigma_T}{4\pi Gm_p} \approx 4 \times 10^8 \text{ yr} \quad (3)$$

The lifetime of stars is related to this by

$$t = \epsilon \left(\frac{L}{L_E} \right)^{-1} t_* \quad (4)$$

ϵ being the efficiency of the energy source¹¹. For massive and supermassive stars $L \approx L_E$; and the expression (4) also gives the time taken for an accreting black hole of mass M to radiate ϵMc^2 .

Suppose that at some early time t , some fraction F of the content of the Universe turns into self-gravitating objects which thereafter each radiate at a rate YL_E until they have radiated away a fraction ϵ of their mass-energy. This will take a time $(\epsilon Y^{-1})t_*$. At that time (assumed $\gg t_*$), the radiation energy density ρ_{γ} will be $\frac{3}{8}\epsilon F\rho_b$, the factor $\frac{3}{8}$ arising from redshift effects. But ρ_b is related to t by $\rho_b = (6\pi Gt^2)^{-1}$ (for $(1+z) > \Omega^{-1}$). If the radiation were to be thermalised, its temperature T_{rad} would

be given by $aT_{\text{rad}}^4 = \rho_r c^2$. When the radiation constant a is written explicitly as $\pi^2 k^4 / 15 c^3 h^3$ this yields

$$\left(\frac{kT_{\text{rad}}}{m_p c^2}\right)^4 = \frac{18}{5} \left(\frac{Gm_p}{e^2}\right) \left(\frac{m_e}{m_p}\right)^4 \left(\frac{e^2}{hc}\right)^{-3} Y^2 \epsilon^{-1} F \quad (5)$$

and, as the photons have average energy $\sim 2.3kT$, $\mathcal{S} \approx [m_p c^2 / (2.3kT)] \rho_r / \rho_b$ which can be written

$$\mathcal{S} \approx \left(\frac{e^2}{Gm_p^2}\right)^{1/4} \left(\frac{m_p}{m_e}\right) \left(\frac{e^2}{hc}\right)^{3/4} Y^{-1/2} \epsilon^{5/4} F^{3/4} \quad (6)$$

This argument can be generalised to situations when Y and F are time-dependent. However, we will always find an expression for $\mathcal{S}$ which involves a fourth root of the ubiquitous 'large number' ($\sim 10^{40}$) multiplied by a set of model-dependent factors whose product is generally somewhat less than unity. It is thus not *ad hoc* that the class of non-primordial models discussed here yields background radiation with $\mathcal{S} \approx 10^8$; on the contrary, equation (6) displays an explicit reason that this should be expected.

Three specific astrophysical arguments pointing towards a phase of pregalactic star formation are: (1) data on their dimensions and spatial distribution suggest that galaxies have developed from density irregularities in the early Universe with a smooth spectrum of form $(\delta\rho/\rho) \propto M^{-\alpha}$ ($\frac{1}{3} \leq \alpha \leq \frac{2}{3}$) (refs 12–15). If this spectrum continued towards smaller scales, then gas clouds of $\leq 10^6 M_\odot$ would already have condensed out—collapsing (and possibly fragmenting) into star-like objects—at $t \leq 10^6$ yr. (This conclusion is insensitive to the Universe's thermal history at earlier times.)

(2) More than 80% of the material in the Universe seems to be 'dark mass' in galactic haloes and clusters of galaxies^{15–17}. This is consistent with the view^{18–20} that most matter was incorporated into one or more generations of O or B stars or supermassive objects which, after a 'brief' ($\sim 10^7$ yr) phase at luminosity $\sim L_E$, collapsed to form dark remnants. These remnants subsequently clustered gravitationally on progressively larger scales, and provided the potential wells in which the luminous content of galaxies eventually condensed¹⁵.

(3) Recent evidence that Fe has almost a solar abundance in the intergalactic medium^{21,22} suggests that pregalactic nucleosynthesis^{19,20} may have occurred.

In this hypothesis, several per cent of the rest mass could have been converted to radiation, through O or B stars with $L \approx L_E$ supernovae, recycling of debris through successive generations of exploding stars or supermassive objects, accretion of dense surrounding gas on to compact remnants, and so on. Thus, even when $t \leq 10^7$ yr ($z \geq 100$), ρ_r/ρ_b can be lifted to the value of equation (2), so that—given adequate thermalisation—it can provide the whole microwave background.

Nucleosynthesis could have supplied heavy elements by $t \cap 10^7$ yr (even if they are not produced 'primordially' in some non-standard 'big bang'). At $z \geq 100$ the mean densities and probable composition throughout the entire Universe resemble interstellar clouds in our present-day Galaxy: we may expect molecules, and carbon or silicate grains. The radiation densities and path lengths are, however, orders of magnitude larger, and if the radiation were thermalised its temperature would be several hundred degrees.

If thermalisation processes can produce a 2.7 K background that is thermal at a present wavelength λ_0 (and we know the background is close to a black body spectrum at least for $\lambda_0 \leq 30$ cm) then the pregalactic medium must have been opaque at wavelengths $\lambda_0(1+z)^{-1}$ where $z \geq 100$ and $T \geq 270$ K.

Three contributors to the opacity are dust, molecules and the ionised component of the medium.

First, dust: the effective absorption cross-section of a grain of radius r can be written $Q(\lambda)\sigma_G$, σ_G being the geometrical cross-section. When $\lambda \gg r$, generally $Q(\lambda) \ll 1$. In fact, for spherical grains one expects $Q(\lambda) \leq Q_{\text{max}}(\lambda) = 4\pi(r/\lambda)$. This means that if $Q(\lambda) = Q_{\text{max}}(\lambda)$ the column density of material needed to yield optical depth unity at a wavelength λ ($\gg r$) is

proportional to λ but independent of r : for grains with typical density $\sim 2 \text{ g cm}^{-3}$ it is $\sim 2/3(\lambda/1 \text{ cm}) \text{ g cm}^{-2}$. The characteristic column density of the Universe at redshift z is $\sim 0.14(1+z)^{3/2}\Omega^{1/2}h \text{ g cm}^{-2}$. To provide optical depth ≥ 1 at redshift z for radiation whose present wavelength is λ_0 the fraction of material in the form of grains must satisfy

$$\frac{\rho_{\text{grain}}}{\rho} \geq 5 \left(\frac{\lambda_0}{1 \text{ cm}}\right) (1+z)^{-5/2} \frac{Q_{\text{max}}(\lambda_0(1+z)^{-1})}{Q(\lambda_0(1+z)^{-1})} \Omega^{-1/2} h^{-1} \quad (7)$$

Q is higher at shorter wavelengths, so whenever equation (7) holds at centimetre wavelength any radiation emitted in the optical or ultraviolet (UV) band will be quickly transformed (perhaps by a sequence of absorptions and re-emissions) into softer radiation and adequately thermalised within the expansion timescale for the Universe.

Second, molecules: if some heavy elements are combined into simple molecules (H_2O , CO, CS, and so on) then the lines corresponding to the rotational transitions will be smeared into overlapping continua by the Hubble expansion. If the levels are in thermal equilibrium (and so populated in accordance with statistical weights when separated by energies $< kT$) the condition for a given molecule, with fractional abundance n_{mol}/n and dipole moment $\mu \text{ Db}$, to provide $\tau > 1$ at $\lambda_0(1+z)^{-1}$ is²⁴

$$n_{\text{mol}}/n \geq 5 \times 10^{-4} \mu^{-2} (1+z)^{-3/2} (\lambda_0/1 \text{ cm}) \quad (8)$$

Third, free-free absorption by the ionised component: the primary sources of the radiant energy may supply UV photons capable of ionising the pregalactic medium. If there is sufficient dust to contribute to thermalisation, it will have a very large optical depth to these photons (see ref. 7). The grains are therefore very efficient at converting the energy of one 'hard' photon into many softer ones. Even though this means that most of the radiation energy density will be in the IR rather than the UV, there may, nevertheless, be enough photo-ionisations to maintain n_e/n at a significant fraction. The high density of soft photons has the interesting consequence that the Compton cooling time $t_{\text{comp}} \approx 3 \times 10^{11} (\tau_{\text{rad}}/270 \text{ K})^{-4} \text{ s}$ may be less than the recombination time $t_{\text{rec}} \approx 2 \times 10^{11} n_e^{-1} (T/270 \text{ K})^{1/2} \text{ s}$. In these conditions, the electrons may have $T_e \approx T_{\text{rad}} (\ll 10^4 \text{ K})$ even when n_e/n is high. Free-free absorption, important only at long wavelengths, will then enhance the thermalisation rather than distorting the spectrum²⁵. The free-free optical depth exceeds unity for

$$\lambda_0 \geq 2 \times 10^2 h^{-3/2} (1+z)^{-1/2} \Omega^{-3/2} \left(\frac{n_e}{n}\right)^{-1} \left(\frac{\bar{n}_e^2}{n_e^2}\right)^{1/2} \times \left(\frac{T_e}{2.7(1+z)}\right)^{3/4} \text{ cm} \quad (9)$$

but the value of n_e is too model-dependent to permit any firm estimate of how important this process is.

One example will show that thermalisation is no great problem for this general scheme. Suppose that $\Omega = h = 1$, and that 0.5% of the mass energy has been converted into radiation when $t \approx 3 \times 10^6 \text{ yr}$ ($z \approx 200$). This satisfies equation (2), and corresponds to a radiation rate of order L_E , assuming that most of the mass is involved in the pregalactic phase of star formation. Thermalisation at $\lambda_0 < 30 \text{ cm}$ would be guaranteed even if only $2.5 \times 10^{-4} (Q_{\text{max}}/Q)$ of the material were incorporated in grains. The actual value of Q depends on grain properties, but small grains of amorphous silicates may have $Q \approx Q_{\text{max}}$ at all wavelengths up to $\sim 1.5 \text{ mm}$ (refs 26, 27) (the wavelength at $z = 200$ corresponding to 30 cm at the present epoch). There is thus no need to invoke grains of exotic shapes or constitutions^{3,4}. Equation (8) suggests that molecules may be important: one requires only 3×10^{-6} (by number) in the form of some molecule with $\mu \approx 1$. The considerations leading to equation (9) suggest that free electrons in the pregalactic medium would be cooled by Compton drag to kinetic temperatures of a few hundred degrees: this provides a favourable environment for molecule formation²⁸.

The detailed physics of the thermalisation (and the epoch when it occurs) are quite uncertain: all that can be argued here is

that the general scheme is plausible in order-of-magnitude terms. The following types of observation are, however, relevant. (1) Background spectrum: although the spectrum should be essentially thermal, deviations from the Planck law might arise if energy were injected at epochs when thermalisation was no longer fully effective at all wavelengths. Also, if some volatile contributor to the opacity with a spectral feature at some wavelength λ_1 were to condense out at a well-defined temperature T_1 , then the background spectrum might now display a feature at wavelength $\lambda_1(T_1/2.7\text{ K})$. (2) Small-scale isotropy: the effective source of the microwave photons reaching us would lie at $z \geq 100$, when they were emitted by a grain or molecule, or scattered by a free electron. The expected amplitude of the temperature anisotropies due to inhomogeneities would be similar to those predicted by the 'hot big bang' picture. An interesting difference in the present scheme, however, stems from the fact that various wavelength-dependent opacities (and not just electron scattering) are important: this means that the angular fluctuations observed at different wavelengths need not be correlated, as the location of the 'cosmic photosphere' depends on wavelength. (3) Galaxy formation and 'missing mass': any observations bearing on galaxy formation, the value of Ω , and the nature of the 'dark' mass in galactic haloes and clusters are relevant to the ideas discussed here.

In conclusion, there are astrophysical reasons for expecting a large radiative output from pregalactic events when $t \leq 10^7$ yr. This radiation could be thermalised, and would now be comparable in temperature to the observed microwave background. It is thus tempting to suppose that essentially all this background originated in this way rather than being a vestige of a hot 'primordial fireball'. The general argument leading to equation (6) then allows us to understand why the parameter $\mathcal{P}$ —whose value is unexplained by the 'hot big bang' theory—is $\sim 10^8$. The arguments pertaining to helium and deuterium are thus our only real clues to the entropy and dynamics at much earlier eras; and the options of non-zero lepton numbers or non-Friedmannian dynamics complicate this issue (as do the uncertainties about nucleosynthesis in the pregalactic objects themselves). The very early Universe thus seems a topic for conjecture rather than consensus while such obscurity veils the first 3 Myr.

I thank Michael Rowan-Robinson, Bernard Carr, Bernard Jones and Simon White for helpful comments.

Venus' rotation and atmospheric tides

VENUS rotates with a period of 243.00 ± 0.04 d retrograde¹. The obliquity, or angle between the spin vector and orbit vector is $178 \pm 1^\circ$ (ref. 1). Both the long period and the near 180° obliquity suggest that the spin has evolved under the influence of tidal torques. Tides raised by the Sun in the body of Venus would de-spin the planet in $\sim 10^8$ yr if no other torques were acting². The final state would be one of synchronous rotation (one side always facing the Sun). So either we are living during the final stages of Venus' tidal evolution, an unlikely circumstance, or else Venus has already reached a stable equilibrium in which other influences balance the solar body tide. It is possible that the Earth has 'captured' Venus into a resonance in which the spin period is 243.165 d. However, for this resonance to be a stable equilibrium, either Venus must have a gravitational field that is ~ 10 times 'rougher' than the Earth's³, a possibility that is largely ruled out by direct observation³, or a third torque must balance the body torque due to the Sun. Tides in the atmosphere driven by periodic solar heating could supply the necessary third torque^{4–6}, but no quantitative theory has previously been published. Such a theory⁷ is presented here, in which we argue that the current rotation is a stable balance between atmospheric and solar body tides.

Because the atmosphere is thin compared with the radius, tidal torques on the atmosphere depend only on lateral variations of atmospheric column density, which is proportional to surface pressure. Although less energy is absorbed at the surface than in the clouds (100 W m^{-2} compared with 500 W m^{-2} at normal incidence)⁸, heating at the ground is the dominant source of surface pressure variations. This follows from the 25-fold decrease in solar diurnal period, from 117 d at the surface to 4 d in the clouds⁸, and the fact that surface pressure oscillations vary roughly as $(\text{period})^2 \times (\text{pressure})^{-1/2}$ at the level of absorption.

It is not difficult to show that the power absorbed by the ground is quickly exchanged with the lower atmosphere. A simple model, representative of more distributed forcing, treats this heating as being confined to a thin layer above the surface. Because of the rigid lower boundary condition, such heating does not excite significant tidal oscillations in the atmosphere above, and fluid parcels within the heated layer remain approximately at constant pressure. The rate of change of column density is therefore

$$\frac{d}{dt} \int_0^\infty \rho dz = - \int_0^{z_0} \frac{\rho}{T} \frac{dT}{dt} dz = - \frac{F}{c_p T_0} \quad (1)$$

where z_0 is the thickness of the heated layer, t is time, ρ is atmospheric density, T_0 is surface temperature, c_p is specific heat at constant pressure, and F is the heat flux (in W m^{-2}) absorbed by the layer. To simulate the finite residence time of a heat pulse in the lower atmosphere we replace d/dt by $d/dt + 1/\tau$ where τ is a thermal time constant associated with boundary layer processes and is in general a function of the forcing frequency.

Equation (1) is solved for the column density as a function of planetocentric latitude, longitude, and time, assuming the lower atmosphere rotates with the solid body. The heat flux F is expressed as a function of these variables by assuming $F = 0$ on the night side and $F = F_0 \cos \zeta$ on the day side, where ζ is the solar zenith angle. The column density is then multiplied by the gradient of the tidal potential, crossed with the planetary radius vector and integrated over the spherical surface to give the net torque on the atmosphere. In a steady state, this torque must be transmitted to the crust. The torque may be resolved into a component parallel to the spin axis, which affects the magnitude ω of the spin angular velocity, and a perpendicular component which affects the obliquity. Defining the angle β as

Fig. 1 Balance of torques on Venus. As only the semidiurnal components of the tides produce a torque, an 'image Sun' is shown diametrically opposite the true Sun, to make the picture symmetrical and to aid visualisation. The Sun is held fixed in this sketch so that Venus is rotating clockwise as seen from north of its orbit plane. The inner oval represents the tidally distorted figure of Venus, while the outer oval represents a surface of constant atmospheric pressure; the outer oval may also be regarded as the surface of an ocean of equivalent mass. Solar radiation raises the air temperature in the afternoon and causes mass to flow to the colder morning region. The high-pressure areas as well as the tidal bulges in the body of Venus are fixed with respect to the Sun (but not with respect to the surface). The gravitational attraction of the Sun, represented by arrows in the diagram, thus exerts contrary torques on the atmosphere and body of Venus.

the supplement of the obliquity, for $\beta \ll 1$ (as at present) one obtains

$$\frac{d\omega}{dt} = \left[\frac{3\pi n^2 r_0^4 F_0}{8c_p T_0 C} \right] \delta(2\omega + 2n) \quad (2)$$

$$\frac{1}{\beta} \frac{d\beta}{dt} = \left[\frac{3\pi n^2 r_0^4 F_0}{8c_p T_0 C \omega} \right] \frac{1}{2} [-\delta(2\omega + 2n) - \delta(\omega + 2n) + \delta(\omega)] \quad (3)$$

where

$$\delta(\sigma) = \sigma(\sigma^2 + \tau^{-2})^{-1} \quad (4)$$

Here n is the orbital angular speed, r_0 is the planetary radius, and C is the planet's greatest moment of inertia.

Equations (1)–(3) have a simple physical interpretation. Heating at the ground causes temperature to rise and column density to fall (equation (1)). Hence there is a mass concentration at the coldest time just after sunrise and a mass deficit at the hottest time just before sunset. The Sun's gravity acting on the sunrise side leads to a torque that tends to speed up the atmosphere (Fig. 1). The relevant frequency $2\omega + 2n$ is that of the solar semi-diurnal tide (equation (2)). The obliquity is affected first by the component of the semi-diurnal tidal torque that acts perpendicular to the spin axis (frequency $2\omega + 2n$), and second by the tides at frequencies ω and $\omega + 2n$ that result from the annual migration (at frequency n) of the sub-solar point across the equator, modulated (at frequency $\omega + n$) by the motion of the Sun relative to the surface (equation (3)).

The gravitationally induced tide that acts on the solid planet leads to expressions of form similar to those above²:

$$\frac{d\omega}{dt} = \left[\frac{3k_2 GM_\odot^2 r_0^5}{2a^6 C} \right] [-\epsilon(2\omega + 2n)] \quad (5)$$

$$\frac{1}{\beta} \frac{d\beta}{dt} = \left[\frac{3k_2 GM_\odot^2 r_0^5}{2a^6 C \omega} \right] \frac{1}{2} [\epsilon(2\omega + 2n) + \epsilon(\omega + 2n) - \epsilon(\omega)] \quad (6)$$

Symbols are defined in ref. 2.) The $\epsilon(\sigma) \approx Q^{-1}$ are phase lags with the same sign as σ that depend on dissipation in the solid planet. $Q(\sigma)$ is the quality factor for oscillations at frequency σ . Values of Q for Venus are unknown, but analogy with the Earth suggests $30 \leq Q \leq 100$ (ref. 9).

According to equations (2) and (5), atmospheric tides tend to increase ω away from synchronous rotation, while solar body tides tend to drive the spin toward synchronism. For $\tau \rightarrow \infty$ (long thermal response time), balance at the current diurnal period of 117 d requires $Q \approx 30$, as shown in Fig. 2. For smaller Q , balance at the current period requires larger Q . Equations (5) and (6) indicate that the current state is stable to obliquity

perturbations provided τ is less than about 2 weeks. The Earth resonance is also stable provided atmospheric and solar body tides balance at a period sufficiently close to the resonant period.

We have shown in which conditions the current rotation might be a stable equilibrium. As shown in Fig. 2, there is also a prograde equilibrium state with a diurnal period of 117 d (spin period ≈ 77 d). The stability of this state may be analysed by substituting $\pi - \beta$ for β and $-n$ for n in equations (2)–(6). Our analysis shows that when one of the two equilibrium states in Fig. 2 is stable to obliquity perturbations, the other is unstable.

Fig. 2 Tidal torques plotted against the diurnal frequency $(\omega + n)(2\pi)^{-1}$ for spin vector parallel to the orbit vector. Atmospheric torques (curved lines) tend to drive the spin away from synchronism, and are shown for values of the thermal time constant $\tau \rightarrow \infty$. The solar tidal torque on the solid body (horizontal line) tends to drive the spin toward synchronism, and is shown for a value of the quality factor $Q = \text{constant} \approx 30$. This choice of Q ensures that atmospheric and solid body torques together drive the spin toward the current diurnal period of 117 d. Torques due to Earth resonances (vertical lines) tend to hold the spin period at the resonant frequencies, and are shown for a value of $(B - A)C^{-1} = 2.2 \times 10^{-5}$, similar to that for the Earth. Here A, B, C are the three principal moments of inertia of Venus, with $A < B < C$. For this amount of gravitational roughness, the Earth torques are too small by an order of magnitude to overcome the solar solid body torques, unless the solar torques and atmospheric torques balance near a resonant frequency. A recent analysis¹ of radar data suggests that the spin period is very close but not equal to that required for resonance with the Earth.

However, in general, other equilibria (both stable and unstable) can occur with obliquities between 0° and 180° . A more complete theory to be presented later indicates that Venus probably originated with a retrograde rotation in order to have evolved to the current retrograde state.

Optical detection of local interstellar particles during an out-of-ecliptic mission

THE contribution to the zodiacal light (ZL) by interstellar grains has been estimated¹⁻³, but, as suggested here, new observations and analyses of the ZL and of the local interstellar medium provide a firmer basis for placing limits on the brightness of the interstellar (IS) relative to the interplanetary (IP) component. The proposed NASA/ESA 'out-of-ecliptic' (or 'solar polar') mission⁴ provides the best and perhaps the only observational method to distinguish between these two components.

To estimate the interstellar dust density, we make the usual assumption that the number density of the interstellar particles (n_{IS}) is related to the local hydrogen number density in the ratio of 10^{-12} (see ref. 5). The local hydrogen density within a few parsecs of the Sun has been observed to be $\sim 0.1 \text{ cm}^{-3}$ (ref. 6) which suggests that we are currently passing through an intercloud region of the galaxy. We infer from this gas density that the IS dust content is about $n_{IS} = 10^{-13} \text{ cm}^{-3}$.

The effect of the Solar System on the ambient IS complex of gas and dust is unknown. Although several mechanisms have been proposed either for capture^{7,8} or the sweeping out of interstellar grains, none of the results are conclusive because of uncertainties in the basic assumptions. The most efficient mechanism for deflecting interstellar particles (if charged) is probably the Lorentz force exerted by the magnetic field associated with the solar wind⁹. Levy and Jokipii¹⁰ estimate the ratio of the Lorentz to the gravitational force (F_L/F_G) at 1 AU to be 10, but their use of an IS particle size of $0.02 \mu\text{m}$ is too small by at least a factor of five for the classical size particles¹¹. If a realistic particle size of characteristic radius $0.12 \mu\text{m}$ is used, a value of F_L/F_G of the order of 0.4 (rather than >1) is derived, and sweeping out of the IS particles should not occur. Given the absence of detailed dust orbit calculations as well as the uncertainties in both the initial grain charge properties and in the possibility of the grains discharging in the IP medium, we base our calculations on the assumption that the grains are neither accreted nor swept out, but that the IS grains in the Solar System are uniformly distributed with a density characteristic of the local IS medium.

We estimate the monochromatic IS contribution to the ZL by scattering of solar radiation from an arbitrary distribution of interstellar particles from the brightness integral¹²

$$Z_{IS} = \int_{LOS} f_{\odot} \left(\frac{R_{\odot}}{R} \right)^2 n_{IS}(\theta) dl \quad (1a)$$

which becomes, for a uniform IS density,

$$Z_{IS} = n_{IS} f_{\odot} R_{\odot}^2 \int_{LOS} \frac{\sigma_{IS}(\theta)}{R^2} dl \quad (1b)$$

where LOS is line-of-sight, $f_{\odot}(R_{\odot}/R)^2$ is the solar flux at a typical volume element at a heliocentric distance R , θ is the scattering angle, $\sigma_{IS}(\theta)$ is the differential scattering cross section of the IS dust, and dl is measured along the LOS. The integral in equation (1b) is calculated from

$$\int_{LOS} \frac{\sigma_{IS}(\theta)}{R^2} dl = \frac{1}{b} \int_{\epsilon}^{\pi} \frac{F(\theta)}{k^2} d\theta \quad (2)$$

where b is the closest solar approach of the LOS ϵ is the elongation angle (see Fig. 1), and k is the wave number ($2\pi/\lambda$) of the incident radiation. For the scattering function $F(\theta)$, we use a dielectric dust model¹³. At a wavelength of $4,400 \text{ \AA}$, the conversion of cgs radiance units to the unit $S_{10}(V)$ (using the observational parameters recommended by Sparrow and Weinberg¹⁴) is

$$S_{10}(V) = 1.2 \times 10^{-9} \text{ erg cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1} \text{ \AA}^{-1} \quad (3)$$

where $S_{10}(V)$ is defined as the radiance produced by a 10th visual magnitude solar (G2V) star per square degree.

According to the model shown in Fig. 1, at the Earth ($b = 1 \text{ AU}$ and for $\epsilon = 90^\circ$), the IS contribution to the ZL is only about $1 S_{10}(V)$. This value is not only below the limit of detectability of $\sim 2-3 S_{10}(V)$ (ref. 15); it is also totally masked by the $200 S_{10}(V)$ contributed by the IP particles. On the other hand, viewing sunwards from a space craft (located at $R = 1 \text{ AU}$) along an LOS parallel to the ecliptic plane and $1/2 \text{ AU}$ above it (out-of-the-ecliptic), the IS brightness estimated from equation (2) for the then appropriate value of $\epsilon = 27^\circ$ is $\sim 28 S_{10}(V)$ which is well above the limit of detectability. Furthermore, this IS contribution may be distinguishable from the IP component.

An observational upper limit to the IS brightness component is established by noting that the ZL is close to solar colour from about $2,200 \text{ \AA}$ to $2.4 \mu\text{m}$ (ref. 16 and refs therein). Since the IS particle scattering is colour (wavelength) dependent in this range, this may be used to establish an upper limit to the IS component. Our calculations are confined to the wavelength spread of the UVB system where more data are available for separating the ZL and the background starlight. The ZL in this wavelength region is known to be solar colour to within about 5%.

Assume that the ZL consists of two components, the IP part which is solar colour and the IS component whose wavelength dependence follows the IS dust model previously cited. Thus if we consider the two wavelengths $5,400 \text{ \AA}$ and $3,600 \text{ \AA}$, the IP component has a spectral ratio $I_{IP}(5,400)/I_{IP}(3,600) = 1$ ($I_{IP} \neq I_{IP}(\lambda)$; I is normalised to solar colour). According to Greenberg and Hanner¹³, the IS component has a spectral ratio $I_{IS}(5,400)/I_{IS}(3,600) = 0.77$ at $\epsilon = 90^\circ$.

The 5% colour variation constraint then implies

$$\frac{I_{IP} + I_{IS}(3,600)}{I_{IP} + I_{IS}(5,400)} = \frac{1 + I_{IS}(3,600)/I_{IP}}{1 + 0.77 \times I_{IS}(3,600)/I_{IP}} \leq 1.05 \quad (4)$$

$$\text{so that } \frac{I_{IS}(3,600)}{I_{IP}} \leq 0.25 \quad \text{or} \quad \frac{I_{IS}}{I_{ZL}} \leq 0.20 \quad (5)$$

This means that no more than about 20% of the total zodiacal light as viewed in the ecliptic and at 90° elongation can be produced by scattering off of interstellar type particles.

Fig. 1 Resulting ZL brightness in $S_{10}(V)$ units per unit distance of closest solar approach along the line of sight from θ to $\theta = \pi$. Inset shows appropriate geometry.

As knowledge of the size and spatial distribution of the IP particles out of the ecliptic is lacking, we derive the maximum amount of IP dust $\frac{1}{2}$ AU off the ecliptic that would still allow the IS component to be distinguished. Let $f \cdot n_{IP}$ be this amount, where n_{IP} is the dust density in the neighbourhood of the Earth and f is the fraction to be determined. As a reference point, the neighbourhood of the Earth has a volumetric scattering cross section of $n_{IP} \sigma_{IP}(90^\circ) = 7.8 \times 10^{-23} \text{ cm}^{-1} \text{ sr}^{-1}$ (ref. 17). For $\theta = 45^\circ$, the scattering cross section $\sigma_{IP}(45^\circ)$ is about $1.77 \sigma_{IP}(90^\circ)$ (ref. 18).

Our minimum distinguishability criterion is that the ratio of the interstellar to interplanetary contributions be greater than 25%. For the case treated above for the interstellar contribution at $\frac{1}{2}$ AU above the ecliptic, then

$$\frac{Z_{IS}}{Z_{IP}} \approx \frac{n_{IS} \sigma_{IS}(45^\circ)}{n_{IP} \sigma_{IP}(45^\circ)} = \frac{7.5 \times 10^{-11} \times 10^{-13}}{f \times 1.77 \times 7.8 \times 10^{-23}} \geq 0.25$$

from which we obtain $f \leq 0.20$.

This value of f is close to but smaller than those derived from a series of models by Giese¹⁹ which produced results consistent with those inferred from observations from the Earth. Most of these models predict the dust density (assumed to be purely interplanetary) to decrease to 20% between heights of 0.5 and 1 AU above (or below) the ecliptic.

These rough calculations suggest there is a real possibility of optically detecting a local IS dust component in the Solar System. Although our criterion of distinguishability is based on colour arguments alone, both polarisation and scattering angle dependence provide additional tools to distinguish between the larger (IP) and smaller (IS) particles. The chance of isolating the IS component increases with decreasing elongation angle. Observations should be made along a line of sight which is parallel to the ecliptic and is as close to the Sun as possible. Unfortunately, such observations can also be inverted; not only the total brightness (Z) be obtained, but when the spacecraft near maximum height the value $n\sigma$ can be directly determined from the measurements²⁰.

Assuming that a positive identification of interstellar dust will be made, we are on the threshold of observing physical parameters of these particles which could previously only be inferred from observations of stellar extinction and scattering in interstellar nebula, which are normally hundreds of parsecs from the local neighbourhood. For example, given a slightly more optimistic estimate (by perhaps a factor of 2) of the local interstellar dust density, we might be able to observe how they are affected by interaction within the Solar System. S. acknowledges the support of NASA and the US Air Force Office of Scientific Research. We thank Dr R. H. Giese and Dr J. L. Weinberg for useful suggestions.

Extent of hot intergalactic gas in the cluster Abell 2218

A SMALL cooling of the microwave background towards the centre of the rich, distant cluster of galaxies Abell 2218 has been detected¹⁻³. This decrement has been attributed to the inverse Compton scattering of photons of the background radiation by electrons in a hot intracluster plasma, as predicted by Sunyaev and Zel'dovich⁴. We report here new observations in several different directions towards the cluster which confirm the earlier results and provide an estimate of the extent of the gas.

The new measurements were made during the period February 1977 to May 1978 at the SRC Chilbolton Observatory, and consist of 199 h of observation at points north and south of the Abell cluster centre⁵ and 54 h further at that position. As in previous measurements^{1,3}, these observations were made at prime focus of the 25-m telescope operated at 10.6 GHz, using a twin-beam system with a beam-throw of 15 arc min in azimuth and HPBW of 4.5 arc min. The receiver incorporated a parametric amplifier with noise temperature about 180 K and bandwidth 250 MHz. The experimental method and data-reduction have been described in detail elsewhere³.

Table 1 shows the coordinates of the positions observed and the temperature decrements measured there. No corrections for the presence of nearby radio sources are needed⁶. The present results are consistent with earlier measurements near dec $66^\circ 20'$ —as discussed by Birkinshaw, Gull and Northover³. The measurement at dec $66^\circ 18'$ was made to check on the strong detections at $66^\circ 16'$ and $66^\circ 20'$ and to furnish another point close to the cluster centre. Its presence leads to an appreciable

Fig. 1 The galaxy strip count, N , in arc min bins and the observed temperature decrement at each point, ΔT , plotted as functions of declination, δ (1950.0 coordinates). The solid line is the ΔT profile of the best-fitting $\gamma = 5/3$, $\xi = -0.15$ atmosphere convolved with the beamshape of the Chilbolton telescope. The linear scale, D , at the distance of the cluster is also marked.

oversampling at the scan centre. In view of the asymmetry of the temperature decrements about the Abell centre at 66° 20', galaxy counts of this region were made from a copy of the Palomar Observatory–National Geographic sky survey red plate. New values for the position of the cluster centre and for the core radius, a , fitted to the assumed total density distribution $\rho(r) = \rho(0)(1 + r^2/a^2)^{-3/2}$ were determined from the counts—these and other cluster parameters are given in Table 2. Strip counts across A2218 and the measured values of the temperature decrement, ΔT , are plotted together in Fig. 1. It is evident that the Zel'dovich cooling is strongest at the cluster centre and decreases rapidly away from this point. A similar scan on a region of blank sky shows no such systematic deviations³.

To evaluate the reliability of the detection of an extended dip in the background, the data of Table 1 were fitted to four models; (1) no effect—a zero value at each point in the scan; (2) a constant effect, ΔT_0 , corresponding to a systematic offset; (3) a point-like 'source' at the cluster centre, parameterised by the peak cooling, ΔT_0 , and convolved with the beamshape; (4) an extended, adiabatic atmosphere with polytropic index $\gamma = 5/3$, and cluster filling factor³ $\xi = -0.15$, again convolved to the beam and parameterised by ΔT_0 .

In the last three cases, the best-fitting values for ΔT_0 were found, and χ^2 were calculated for all the models. The results were: (1) $\chi^2 = 83.4$, 5 d.f.; (2) $\chi^2 = 20.1$, 4 d.f.; (3) $\chi^2 = 13.7$, 4 d.f.; (4) $\chi^2 = 6.4$, 4 d.f. These values are such that all but the last hypothesis can be rejected at the 1% level (the probability of a greater value of χ^2 for model 4 is about 0.18). Hence our data constitute strong evidence for an extended atmosphere in Abell 2218. The ΔT values corresponding to the best atmosphere of type 4 are plotted in Fig. 1. The central temperature and density required to produce the observed X-ray flux density and temperature decrement are given in Table 2. The values of these parameters are uncertain by a factor ~ 3 due to the range of possible values of ξ .

Because the cooling effect, X-ray emission and galaxy distribution are strongly correlated in position, we conclude that the evidence for a microwave background decrement associated with a hot intracluster medium in Abell 2218 is now overwhelming.

We thank the director of the SRC Appleton Laboratory for the facilities provided at the Chilbolton Observatory.

Limited solubility of iron in the Sun's interior

STRIPPED iron nuclei in a hydrogen plasma under central solar conditions, according to the classical Debye–Hückel model, would undergo phase separation for concentrations well below the cosmic abundance value. The higher concentration corrections, needed to characterise the iron-rich phase, lead to enhanced solubility for a simplified model where the electrons form a uniform background. Support for an iron-rich phase coalescing in the solar interior requires more accurate treatment of bound and partially bound electrons in such a mixture. The results of the Debye–Hückel model where the electrons are treated discretely and as a continuum, are reported here and support the possibility of phase separation. The physical cause of that phase separation is simply that the potential energy is lower in the separated phases than in the mixture because the local charge neutralisation is much better satisfied in the two separated phases.

Recent phase separation calculations for mixtures of stripped atoms^{1–3} suggest that highly charged nuclei would have limited solubility in a hydrogen plasma under conditions found in stellar interiors. These results suggest that highly ionised iron would precipitate out in the solar interior and coalesce in the centre. Should this occur and lead to a reduction of the iron concentration near the thermonuclear burn region, by an order of magnitude below the cosmic abundance value (2.5×10^{-5} ionic mole fraction), the existing neutrino dilemma might be resolved. It is estimated⁴ that such a concentration reduction would lower the opacity, and hence the temperature, sufficiently to significantly reduce the probability of fusion of α particles that generates the nuclei whose neutrino emission is being monitored. This paper presents various simplified models for the iron, hydrogen plasma phase diagram which explore this possibility.

A realistic calculation of the phase diagram is difficult for two reasons. The most important difficulty is that of accurately treating the bound and partially bound electrons of iron. At the solar interior temperature of about 1.5 keV and pressure of 10^5 Mbar, the two 1s electrons (with ionisation potentials of over 8 keV) are still bound whereas the eight 2s and 2p electrons (with ionisation potentials below 2 keV) are partly bound.

Fig. 1 The coexistence (solid lines) and instability (dashed lines) curves for an element of charge 26 (upper set of curves) and of charge 20 (lower set of curves) in a hydrogen plasma according to the Debye-Hückel theory. The ionic mole fraction of the element, y_1 , is plotted against the reduced temperature, T^* , at various pressures (Δ , 10^3 Mbar; $\square$, 5×10^4 Mbar; $\circ$, 10^4 Mbar). Points A and A' are, for example, two coexisting phases in the charge 26 system. The hatched area represents central solar conditions.

Of course, the bound-free transitions of these electrons lead to the large contribution to the opacity of a hydrogen plasma of even a very small amount of iron. This problem is crudely dealt with here by ignoring the partly bound electrons and considering the bound electrons merely to reduce the point nuclear charge to give some effective point charge. This crude approximation may not as seriously affect the calculation of the coexistence curve as might at first be expected. Errors tend to cancel as the chemical potential of iron in the iron-rich phase is equated to that in the iron-poor phase, where in both phases the electron density is nearly the same. In previous calculations³, when the polarisation of the electron gas by the ionic charge distribution was treated by perturbation theory the phase diagram was not drastically modified.

The second difficulty concerns accurate treatment of concentrated solutions of electrolytes, such as the iron-rich phase. The dilute phase can be adequately dealt with by the classical Debye-Hückel theory of a mixture of three components (iron nuclei with an effective charge, protons and electrons) as can be seen from the ratio of the ion sphere radius to the Debye length being less than unity (see Table 1). The electrons in the solar interior are very non-degenerate, as can be seen from the calculated Fermi temperature (Table 1). To avoid dealing with the concentrated solution, the instability curve was calculated in the dilute phase from the vanishing of the second derivative of the free energy with respect to iron concentration. This limit turned out, however, to be too loose to give insolubility near solar concentrations, so we had to deal with the iron-rich phase by corrections to the Debye-Hückel theory.

These corrections require a quantum mechanical treatment of the electrons to avoid divergences which arise if bound state contributions are ignored. These corrections can be included using an activity expansion⁵ but are of such complexity that they have not yet been calculated for this system. Instead, a model treating the electrons in the uniform background approximation was explored. Comparison with the discrete case discussed earlier, where in both cases the ions were treated in the Debye-Hückel approximation, was satisfactory, demonstrating the insensitivity of the coexistence curve to the electron distribution. For the uniform electron model it was then relatively easy to calculate the higher concentration⁶ corrections and show how they affect the coexistence curve. Even these corrections fail to extend the coexistence curve into the solar concentration region since the series fails to converge for the coexisting iron-rich phase.

Having exhausted so-called analytical methods, the uniform electron background model can be extended by numerical techniques using either the Monte Carlo or molecular dynamics method. These calculations are fairly cumbersome, so they will

be used initially to check how well the hypernetted chain integral equation represents the mixture of charged nuclei in a neutralising rigid uniform electron background. If that integral equation were also adequate when the charge difference between the species is extreme, as in the present case, it would reduce the numerical work required. The object of these calculations would be to determine the solubility for an iron ion of charge 24, corresponding to two bound K electrons, in a hydrogen plasma in which the polarisation of the partially bound L electrons will be treated by linear dielectric response theory.

For a mixture of N_2 protons and N_2 ions of charge Z_1 and hence $N_1 Z_1 + N_2$ classical electrons in a volume Ω , the low density value of the free energy is given by the Debye-Hückel theory⁷, which requires that the ratio of the ion sphere radius r , to the Debye length, λ , to be < 1 .

The Debye length is given by $\lambda^{-2} = 4\pi\rho e^2 Z^2 / kT$, where $\rho = 3/4\pi r^3$ is the total particle density and defines the ion sphere radius. $Z^2 = X_1(Z_1^2 + Z_1) + 2X_2$, where X_1 is the concentration per particle or $X_1 = N_1/N$ with $N = 2N_2 + (1 + Z_1)N_1$. We define the concentration per ion as $y_1 = N_1/(N_1 + N_2)$.

The pressure and Gibbs free energy thus derived are used to investigate phase separation at constant temperature and pressure, by the double tangent construction which is equivalent to equating chemical potentials. The instability points determined by setting the second derivative of the Gibbs free energy, with respect to mole fraction, equal to zero, always lie within the concentration range determined from the double tangency construction. The instability curve for the low concentration phase can be calculated over a wider concentration range than the phase diagram, as shown in Fig. 1, because it is not limited by the validity of the Debye-Hückel approximation for the coexisting concentrated phase. However, the applicability of the Debye-Hückel theory as given by the r/λ criterion for the free energy is severely tested when a second derivative of the free energy is taken, indicating that r/λ must be $\ll 1$ before the second derivative is adequately given by the low density theory. But as shown in Fig. 1, the instability criterion is not restrictive enough. For phase separation to occur, solar conditions must lie in the two phase region, that is below the solid curves. If solar conditions are also below the dashed curves, the instability criterion would have been sufficient.

The coexistence curve and instability curve for $Z_1 = 26$ and $Z_1 = 20$ are displayed in Fig. 1 at various pressures. The results are nearly pressure independent when plotted as a function of the reduced temperature, $T^* = kT/e^2\rho^{1/3}$, because the equation of state is almost that of an ideal gas. This is indicated by the large value of T^* which is a measure of the ratio of kinetic

Fig. 2 The coexistence curves for an element of charge 26 in a hydrogen plasma according to the Debye-Hückel theory (curve 1), according to the Debye-Hückel theory for the ions but with the electrons treated in the uniform background approximation (curve 2), according to the same model as represented by curve 2 except that the first order concentration corrections as given by Abe are included (curve 3) and according to the previous model except that the second order concentration corrections are also included (curve 4). The ionic mole fraction y_1 , is plotted against the reduced temperature, T^* , at a pressure of 5×10^4 Mbar. Points B and B' are, for example, two coexisting phases.

applied excellence

Advanced techniques in routine use at The Radiochemical Centre

Described below are just two examples of the many up-to-date techniques, which have been pioneered or applied for routine use at The Radiochemical Centre. These developments are part of our constant endeavour to maintain our position at the forefront of the specialised field of tracer methodology, so that we can continue our supply of radiochemicals of the highest quality and technical specifications.

Distribution of labelling in tritium compounds

Modern techniques for the production of tritiated compounds are more sophisticated than those used in the early days of tritium labelling, and produce compounds labelled in specific positions rather than generally labelled. Nevertheless, it is necessary for many tracer applications of tritium compounds to know the *precise* position and configuration of the tritium labels. Traditional chemical methods of doing this are tedious and time consuming and subject to considerable error, and so the routine supply of such information has until recently not been possible.

The Radiochemical Centre, in collaboration with the University of Surrey, has developed over the past eight years the technique of tritium nuclear magnetic resonance (tnmr) spectroscopy for this purpose. This method is much quicker and more accurate than the traditional chemical or biochemical methods for determining distribution of tritium labelling.

It is now used routinely to establish the distribution of tritium labelling produced by the usual methods of tritiation employed at The Radiochemical Centre. We supply accurate details as to the position and configuration of the tritium labels for an increasing number of our labelled compounds.

Circle No. 11 on Reader Enquiry Card

High performance liquid chromatography (HPLC)

This relatively new development of column chromatography is carried out using high efficiency microparticulate column packings of closely defined size.

Chromatography is carried out under pressure to ensure good flow rates and reduce diffusion of separated compounds. Dead volumes are kept to an absolute minimum. The result is that many separations can be carried out more quickly and with better resolution than with previously used chromatographic methods such as thin-layer chromatography or conventional column chromatography.

Work aimed at developing the applications of this method to radiolabelled compound separations is still in progress, but The Radiochemical Centre is already using the technique in many of its production processes, and in analytical applications. The result is purer compounds for the customer and greater efficiency of working.

The example illustrated below illustrates the clear superiority of HPLC when used as an analytical tool. The mixture used comprised the tritium labelled mono-, di- and triphosphates of adenosine, cytidine, guanosine and uridine, and all are clearly separated in the HPLC system.

‡ The Debye-Hückel pressure includes the ideal gas term, all pressures are measured in Mbar.

to potential energy. The solar conditions in Fig. 1 indicate that extending the coexistence curve would predict considerably smaller solubility than the cosmic abundance value of 2.5×10^{-5} in which the iron-rich phase would contain about half iron and half hydrogen. Even for the extreme case of $Z_1 = 20$, believed to represent the lowest possible ionisation state of iron under interior solar conditions, phase separation might be marginally inferred. The Debye-Hückel theory predicts, as expected, that decreasing the effective iron charge lowers the critical temperature and increases the critical concentration. The prediction is, therefore that in any stellar interior in which the difference in charge between iron and any other charged species is >20 , iron will be less soluble than its cosmic abundance. In the Sun the temperature drops at midradius sufficiently for iron ionisation to be reduced below 20 and hence beyond this midpoint, iron would be expected to be soluble.

Because the dilute Debye-Hückel theory is insufficient and the rigorous corrections require the electrons to be dealt with quantum mechanically, a uniform background electron gas approximation was explored for which concentration corrections can be more easily calculated. In that case, the free energies of the ions and electrons are additive. The electrons are treated as an ideal Fermi gas whose thermodynamic properties involve the usual Fermi-Dirac integrals⁸. For the temperature and pressure of interest here, the electron gas is nearly classical. The ions are first treated in the Debye-Hückel approximation, and the case for $Z_1 = 26$ is compared in Fig. 2 with the earlier calculation where the electrons were treated as an ionic species. The similar coexistence curve encourages the uniform background model to be extended to higher densities.

The straightforward inclusion of the first order correction^{5,6} leads to a rather large shift of the coexistence curve as shown in Fig. 2. Hence, it was necessary to consider the second order correction. The coexistence curve calculated including this correction to the free energy, is the lowest curve in Fig. 2 and shows that the shift in the critical temperature is considerably smaller than with the first correction. Extrapolating this series from these limited results leads to an estimated critical T^* , for the uniform electron gas case of about 20. This T^* is larger than that for central solar conditions, which is necessary for insolubility exceeding cosmic abundance.

Table 1 shows the convergence of the series for the pressure, at pressures corresponding to the region of thermonuclear burn and at the centre of the Sun. In the dilute iron phase, the electron and ion pressure are nearly equal, corresponding to ideal gas conditions of a hydrogen plasma, and the series convergence is excellent. In the coexisting iron-rich phase, the electron pressure exceeds the ion pressure due to the large number of electrons ionised from a high Z element. Furthermore, the convergence of the series is such that it is not possible to calculate the coexistence curve reliably for a more iron-rich

phase. Nevertheless, the calculations presented here suggest phase separation under solar conditions. More realistic models are needed to confirm this suggestion.

Alfvén waves generated by an inverted plasma energy distribution

OBSERVATIONS from the geosynchronous spacecraft ATS6 of magnetic oscillations transverse to the Earth's magnetic field in the presence of a plasma ion distribution with a 'bump-in-tail' form are reported here. We argue that the oscillations are Alfvén waves, that the non-monotonicity (that is, population inversion) of the energy distribution provides a source of free energy for the oscillations, and that the particle-wave interaction is through bounce resonance¹. The data reported here comes from the UCLA fluxgate magnetometer² and the UCSD particle detector which measures ions and electrons with energies from 10 eV to 80 keV (ref. 3). The magnetometer data are displayed in a field aligned coordinate system in Fig. 1. A wave with an amplitude of about 5 nT and a period of about 100 s is present. The strongest signal is in B_x , the component in the meridian and perpendicular to the background field, B . The magnetic signal seems typical of a class of pulsations with short wavelengths across B seen in the local afternoon on ATS6⁴. These particular observations were made near 1500 LT.

Figure 2 shows the ion-velocity distribution, f , as a function of energy, W . The curves show the mean distribution for

Fig. 1 The magnetic field data from the geostationary spacecraft ATS6, are presented in a mean field aligned coordinate system in which B_x is measured along the mean field direction, obtained by forming a 10 min sliding average of the data. B_x is in the plane containing the Earth-satellite line and B_z . The B_z baseline is 130 nT. One division on the ordinate is 2 nT. Peak to peak amplitudes in B_x are of order 5 nT.

Fig. 2 Ion velocity distribution functions measured on ATS6 during the three half-hour periods during which the magnetic oscillations were observed. Although the instrument cannot distinguish ion species directly, we assume that the ions are protons.

three successive half-hour segments. The distribution remained largely unchanged through the course of the event. There is a minimum where $W \sim 1$ keV and $\partial f / \partial W > 0$ in the range $1 \text{ keV} < W < 10 \text{ keV}$. Any 'filling' of the distribution with time is probably due to spatial structure in the ion distribution, since the ions are drifting in the opposite sense to the spacecraft motion in this region⁵. In a collisionless plasma, diffusion in energy to fill the minimum may be accomplished by particles being resonantly scattered by a plasma wave. The observed frequency is of the order of the frequency of the bounce motion of an ion with a few keV energy in the Earth's mirror field and so the relevant resonant interaction is bounce resonance¹.

The low frequency and the quasi-transverse nature of the magnetic signal suggest that the wave present is an Alfvén wave with standing structure along the geomagnetic field. This idea is confirmed by more detailed investigation. The UCSD detector measures a complete energy spectrum every 24 s, and the effects of the wave can be detected in the low energy proton channels. The variation in low energy proton count is due to a drift velocity proportional to the wave electric field⁶ and using procedures similar to those used by Hughes *et al.*⁷ we found the wave electric field was in quadrature with the magnetic signal thus confirming the standing nature of the wave. The relative phase also showed that the standing wave was an even harmonic (a mode with an electric field node at the equator) and the observed frequency together with an estimate of the Alfvén speed, based on observed densities, suggests it should be the second harmonic. The symmetry of the signal about the equator is crucial in suggesting bounce resonance is the source; the first descriptions¹ of the mechanism pointed out that even harmonics would be generated. Other hydromagnetic wave sources are likely to generate the fundamental. The wavelength of the signal across the field is short, since magnetic pulsation activity on the geosynchronous SMS1 spacecraft (19° E of ATS6) and SMS2 (10° W of ATS6) did not correlate with the

ATS6 signal. This shows signals are relatively localised and rules out the Kelvin-Helmholtz instability as the energy source⁴. Spectra and coherence information from the three spacecraft for this event are shown in Fig. 4 of ref. 4.

The condition for a particle with bounce frequency, ω_b , and E-W drift speed $\tilde{\omega}_d$ to be in bounce resonance with a wave with frequency ω and E-W angular wave number m is

$$\omega - m\tilde{\omega}_d = N\omega_b$$

where N is an integer¹. Here we are interested in $N \sim 1$ and if the Doppler shift $m\tilde{\omega}_d$ is significant the E-W wavelength needs to be relatively small¹ (of the order of the equatorial Larmor radius of a resonant particle).

A particle's energy in an Alfvén wave increases due to the wave electric field at a rate $q\mathbf{E} \cdot \mathbf{v}_d$, where $\mathbf{v}_d$ is the E-W drift velocity due to curvature and ∇B drifts. We can estimate the energy diffusion coefficient due to this acceleration for a particle in resonance with a wave of bandwidth, $\Delta\omega$,

$$\langle q\mathbf{E} \cdot \mathbf{v}_d \rangle^2 \Delta\omega^{-1}$$

where the brackets denote the mean value seen over a particle bounce. We can estimate the wave electric field as $\sim 5 \times 10^{-1} \text{ mV m}^{-1}$ from the data and substitute this value into the diffusion coefficient to show that the time scale for diffusion to fill the hole in the energy distributions is $\sim 5 \times 10^5 \text{ s}$ that is a time much longer than the time scale of particle motions through this part of the magnetosphere.

The filling of the distribution seen in Fig. 2 cannot, therefore, be due to the waves. Cowley⁵ has shown how the magnetospheric convection pattern can lead to such distributions and, as indicated earlier, the protons are drifting in the opposite sense to the spacecraft motion. Much as one can estimate a diffusion time one can parametrise the energy exchange between particles and waves by estimating the contribution to the growth rate of the resonant ions. Estimates⁸ show that this is proportional to the resonant particle pressure:

$$\gamma/\omega \approx P_{\text{res}}/B^2/2\mu_0$$

which gives

$$\gamma/\omega \sim 10^{-2}, 10^{-3}$$

for observed parameters. These figures are of a similar order to the expected rates of ionospheric damping on the dayside of the magnetosphere⁹ and it seems the quasi-steady signal is maintained by energy being fed from particles to the wave to be lost in the ionosphere. The amplitude of the waves would then be sustained by the supply of ions drifting from the night side.

There are also low energy electrons in bounce resonance with the wave. Although there are more electrons than ions, their pressure is much lower as the resonance condition implies they have the same velocity as the ions.

In conclusion these observations show the first direct evidence of generation of hydromagnetic waves through bounce resonance with a non-equilibrium distribution, which theory first suggested 10 years ago^{1,10}. In this observation the distribution of ions was non-monotonic with energy. Theory shows that this is not a necessity; steep spatial gradients in the ion distribution can similarly drive waves. However, both observation¹¹ and theory⁵ indicate the regular occurrence of non-monotonic ion distributions in the afternoon-evening magnetosphere. These may be the source of many of the pc4 pulsations characteristic of this sector at geosynchronous orbit.

A fast interferometric chopper for neutrons and X rays

FAST neutron choppers have been considerably developed in the past few years. The commonly used choppers are either rotating massive objects through which appropriately shaped neutron channels are cut¹ or crystals whose diffracting power may be modulated by magnetic fields² or dynamic strains³. All these devices suffer from practical limitations of speed, poor duty cycle and the consequent loss of intensity. We describe here our use of a scanning Bragg reflecting crystal interferometer as a fast chopper. Although they have been used with X rays, crystal interferometers work equally well with neutrons⁴. The interferometer is used as a phase sensitive neutron switch, in which a crystal translation of 0.96 Å is sufficient to redirect the beam. At larger translational amplitudes the interferometer has a corresponding multiplex advantage over other neutron choppers. Two of these interferometric neutron choppers could be used to construct a Fourier transform neutron spectrometer with 1,000

Fig. 1 The monolithic scanning X-ray interferometer which is cut from a perfect single crystal of silicon. The ferrite disk F is glued to a U-bracket which drives the elastic transverse stage and forces are generated by the electromagnet E. X-ray beam paths through the interferometer are indicated by shaded areas. 220 Bragg reflections provide beam steering in the splitter crystal S, mirrors M and analyser A. The interferometer is described in detail elsewhere⁵. Scale, 10 mm.

Fig. 2 The electronic drive system showing how the oscilloscope display is generated

times the resolution of competing spectrometers. With a pulsed source a single interferometric chopper could be used to construct a time of flight spectrometer which would provide high resolution even with fast neutrons.

The interferometer construction is shown in Fig. 1. The monolithic scanning interferometer^{5,6} is driven by the force between the electromagnet E and the ferrite disk F. The three wafers S, M, A which form the X-ray or neutron interferometer, are all part of the same monolithic perfect crystal. Coherent beam steering is achieved with the 220 and $\bar{2}\bar{2}0$ Bragg reflections indicated in the ray diagram. A is connected to S and M through the monolithic elastic transverse^{5,7} which allows the translational degree of freedom of A parallel to the [110] direction. When the analyser A travels a distance of 1.92 Å in the [110] direction which is normal to the Bragg planes, one fringe is observed in each of the two output beams.

In the case of zero absorption the output beams are complementary (conservation of photons or neutrons in the analyser A). For example, when the analyser translation x is pd the forward beam T has maximum intensity, whereas for $x = (p + \frac{1}{2})d$ the intensity maximum is in the deviated R-beam. Here, p is an integer and d is the Bragg spacing: 1.92 Å for the 220 Bragg reflection from silicon. The intensity N is given by

$$N = N_0 + N_1 \sin(2\pi x/d)$$

If $\dot{x} = 2 \text{ mm s}^{-1}$, which is easily achieved, then we would observe complementary output beams, amplitude modulated at 10 MHz, and with 100% duty cycle as no neutrons are absorbed in the interferometer. In practice, the fringe contrast observed with X rays may be 0.95 while for neutrons^{5,8} the best contrast observed has been approximately 0.85. Both would be 1.00 in an ideally perfect interferometer with zero absorption.

In considering the design and use of mechanical systems, one needs to know the system response to disturbances. The intensities available from both X-ray and neutron sources are so low that we could not measure the impulse response directly. We were, however, able to measure the simple harmonic frequency response directly with X rays using 30-s integration time.

Figure 2 shows the experimental arrangement and Fig. 3 demonstrates the fringes observed near a mechanical resonance in the system at 10.8 kHz. The fringe resolution is limited to about 500 ns by the time base trigger-jitter and by the frequency response of the oscilloscope z-modulation. When operating near the fundamental translational resonance which occurs at 1,420 Hz we found no loss of fringe contrast, which indicates that only the pure translation mode was excited.

The interferometer was tested with molybdenum $K\alpha_1$ radiation for which the available intensity from a conventional laboratory source is a few thousand photons per second. Each photon detected (Fig. 2) produces a bright spot on the oscilloscope screen. With 3,000 speed polaroid film it was necessary to pulse the z-modulation for 500 ns to record an image and this

Fig. 3 X-ray fringes produced by the system outlined in Fig. 2. The finest fringes correspond to 500 ns chopping times and resolution is mainly limited by the oscilloscope performance. Each bright spot in the photograph corresponds to one detected X-ray photon. Scale, 100 μ s.

limits the present time resolution of the detector system. In Fig. 3, the interferometer was driven with a sinusoidal current of frequency ω . In a practical neutron chopper pulsed or triangular waveforms might also be used. So that the fringe system is easily visualised, the y -displacement consists of the sum of the electromagnet drive voltage and an incommensurate triangular voltage. The observed fringe spacing is, of course, not constant. The applied force is proportional to the square of the magnet current, and the observed fringes show the displacement as a function of time. The force F is given by

$$F = KI_0^2 \sin^2 \omega t = \frac{1}{2} KI_0^2 (1 + \sin 2\omega t)$$

where K is a constant and the force repetition rate is seen to be twice that of the driving current. This is clearly seen in Fig. 3 where the periodicity of the fringe pattern is twice that of the current signal. Since one fringe occurs for a displacement of 1.92 $\text{\AA}$ we were able to trace the complete frequency response of the chopper from these photographs. Thus, amplitude, stored energy and phase shift can all be measured as functions of frequency. The two fringe patterns were obtained near the 10.8 kHz mechanical resonance with only 15 mW of magnet power. The phase shift between the mechanical motion and the electromagnetic force near resonance can be clearly seen as can the ~ 500 ns spacing of the finest visible fringes. At that point the speed of the analyser wafer is 1.92 $\text{\AA}$ per 500 ns or 0.4 mm s^{-1} .

It is not unreasonable to use up 1,000 times more power in the driving electromagnet. With only 15 mW of power, the present chopper is already faster than any alternative. There are two ways in which the potential performance can be exploited. Either high power interferometric neutron chopping can be achieved on the sub-ns timescale or very precise neutron gating could be attempted on the μ s and longer timescales. The former would be attractive for extreme resolution multiplexed neutron spectroscopy using high flux neutron sources; the latter might be more attractive at pulsed sources, such as the spallation neutron source.

In future developments it will be desirable to have both positive and negative force generators. Experiments using double magnet systems and permanent magnets in place of the ferrite disk are in progress. Both systems will permit push-pull operation. The strain gradients inherent in systems which rely on

Bragg reflections from sets of standing or travelling ultrasonic waves³ have caused great problems. Because of the neutron samples' spatial and/or temporal crystal inhomogeneities, these systems are limited to frequencies well below 100 kHz with crystal thicknesses of the order of 1 mm. Provided that the interferometer wafer S, M and A undergo pure uniform translation there is no similar limit on their performance as each crystal component remains homogeneous and strain-free. The neutrons are, of course, Doppler shifted in the analyser and this is equivalent to rotating the analyser. At 2 mm s^{-1} the rotation for thermal neutrons is ~ 0.5 arc s but the Bragg angle 2θ is not changed to first order. Since the range of Bragg reflection is ~ 2 arc s at 2 $\text{\AA}$ wavelength, the chopper could be 'returned' by rotating the analyser. At much higher crystal speeds it may become necessary to correct for the second order Doppler shift in the Bragg angle by changing the temperature of the analyser crystal. Higher order Bragg reflections can be used to provide multiplexed channelled spectra and to achieve even faster chopping rates.

At present the best on-off ratio for neutrons^{4,8} is at least 6 but with more perfect crystals this should exceed 10. Although the new chopper might have advantages in experiments to determine h/M for the neutron⁹, and in providing precisely sinusoidal neutron modulation in Fourier time-of-flight spectrometers¹⁰; other possible applications are still only in the discussion stage.

We thank Drs Hauer, Mikula, Michalec and Stirling, and the staff of the Rutherford Laboratory for helpful discussions.

Hydrogen bond dynamics in solution

THE key to understanding the broad but featureless $\nu_s(XH)$ absorption bands of hydrogen-bonded species in solution has been the recognition by Bratos that the $\nu_s(XH \cdots Y)$ hydrogen bond stretching mode has a pronounced stochastic character, and that the $\nu_s(XH)$ mode rapidly loses its phase coherence as a result of its strong anharmonic coupling to the $\nu_s(XH \cdots Y)$ mode¹. This idea has been further developed by Yarwood and Robertson^{2,3}, who treat the dynamics of the ν_s mode more precisely than does Bratos. The most detailed prediction of these theories is that the amplitude of modulation of the $\nu_s(XH)$ mode should be proportional to the r.m.s. amplitude of the ν_s displacement coordinate r_2 , and should thus vary with temperature as $(\coth(\hbar\omega_2/2kT))^{1/2}$, where $\omega_2 (= 2\pi c\bar{\nu}_s)$ is the angular frequency of the ν_s mode. We report here an experimental confirmation of this prediction for a dilute solution of self-associated CD_3OH in freon 11. We also investigate how the dynamics of the hydrogen bond vibration change as the solvent freezes, and we present evidence that at liquid helium temperature the $\nu_s(XH \cdots Y)$ mode can be regarded as a quantum-mechanical stochastic oscillator executing a strongly overdamped zero-point motion.

Fig. 1 Observed (continuous line) and fitted (crosses) spectrum of self-associated CD_3OH in CFCl_3 ; temperature, 240 K; concentration, 0.2 M. There is a further broad absorption band on the low frequency side, not accounted for by the theory, which may be due to multimeric species. This makes it difficult to determine the low frequency baseline satisfactorily. The absorption band at $3,650\text{ cm}^{-1}$ is due to free CD_3OH ; its intensity increases with increasing temperature. The data were zero-weighted below $3,100\text{ cm}^{-1}$ and between $3,625$ and $3,675\text{ cm}^{-1}$ during curve-fitting.

Yarwood and Robertson^{2,3} assume that the ν_o displacement coordinate r_2 satisfies the Ornstein–Uhlenbeck stochastic differential equation⁴

$$\ddot{r}_2 + \gamma \dot{r}_2 + \omega_2^2 r_2 = m_2^{-1} F(t) \quad (1)$$

and, by applying Kubo's theory of a randomly modulated oscillator⁵, show that the autocorrelation function of the $\nu_s(\text{XH})$ transition dipole moment is

$$\phi(t) = \exp \left\{ -\Delta^2 \int_0^t (t-x) \psi(x) dx \right\} \quad (2)$$

where ψ is the autocorrelation function of the Ornstein–Uhlenbeck stochastic process⁴. The amplitude of modulation Δ of the ν_s mode is given by

$$\Delta = K_{112} \langle r_2^2 \rangle^{1/2} / m_1 \omega_1 \quad (3)$$

where K_{112} is an anharmonic coupling constant, and the characteristic time τ_c of the modulation is given by

$$\tau_c = \gamma / \omega_2^2 \quad (4)$$

Equations (2)–(4) give a good account of the experimental $\nu_s(\text{XH})$ absorption band profiles of phenol–acetonitrile and phenol–dioxan complexes in solution in carbon tetrachloride, correctly predict the changes which occur on deuteration, and enable the effect on the bandshape of changing the solvent to be understood⁶.

The most stringent way to test the theory, however, is to study the temperature dependence of the $\nu_s(\text{XH})$ bandshape⁷. According to equations (3) and (4), Δ should vary as $(\coth(\hbar\omega_2/2kT))^{1/2}$, while τ_c , being proportional to the microscopic viscous damping constant γ , should increase rapidly as the temperature is reduced. To investigate this, we have recorded digitally the $\nu_s(\text{XH})$ absorption bands of self-associated CD_3OH in freon 11 (CFCl_3) between 280 and 160 K, and have estimated the parameters Δ and τ_c by a nonlinear least-squares analysis of the bandshape. A typical $\nu_s(\text{XH})$ band with its theoretical reconstruction superimposed is shown in Fig. 1, and a summary of the parameter estimates is given in Table 1. The method of analysis was similar to that described previously⁶,

except that $\bar{\nu}_o (= \omega_2/2\pi c)$ was treated as a fixed parameter with a value of 100 cm^{-1} . This is a compromise between the value of 80 cm^{-1} (or at most 100 cm^{-1}) suggested by Lake and Thompson⁸, and that of 120 cm^{-1} found by Zelsmann (personal communication).

The regression $\Delta = a + b (\coth(\hbar\omega_2/2kT))^{1/2}$ is close to linear, with a correlation coefficient of 0.99. The intercept a does not differ significantly from zero at the 95% confidence level. This strongly supports equation (3), and shows that the contribution to the broadening from mechanisms other than vibrational phase relaxation is small. As expected, the viscous damping constant γ increases with decreasing temperature; however, the temperature dependence of γ cannot be well represented by a law of the form $\exp(A/kT)$, particularly at the lower temperatures. (Although this may be partly due to the uncertainty in the value of ω_2 , previous work⁶ has shown that γ is not related to the macroscopic viscosity of the solvent.) The Kubo parameter $\tau_c\Delta$ increases somewhat as the temperature is reduced, but the system is far from the slow modulation limit ($\tau_c\Delta \gg 1$) at all temperatures above 160 K, and the $\nu_s(\text{XH})$ absorption band profiles differ markedly from gaussian shape.

Below 160 K the solution freezes to form a vitreous solid. On freezing, the bandshape changes dramatically: the halfwidth at 170 K is 175 cm^{-1} , and at 150 K it is 210 cm^{-1} (see Fig. 2). However, analysis of the bandshape shows that the amplitude of modulation continues to decrease, in a manner consistent with equation (3), as the temperature is reduced to 150 K: there is no discontinuous change in the amplitude of modulation at the transition point, even though the $\bar{\nu}_s(\text{XH})$ frequency abruptly shifts upwards by several wavenumbers on freezing. (The general trend is for the $\nu_s(\text{XH})$ frequency to shift steadily downwards with decreasing temperature.) On the other hand, τ_c increases from 0.046 ps to 0.40 ps, $\tau_c\Delta$ from 0.83 to 7.0, and $\gamma/2\omega_2$ from 0.44 to 3.9.

Although these estimates are imprecise, particularly at the lower temperature where the errors are of the order of 10%, they do show qualitatively how the dynamics of the hydrogen bond change as the solvent freezes. In the solid the $\nu_o(\text{XH} \cdots \text{Y})$ vibration is heavily overdamped, and relaxes slowly. The large value of the Kubo parameter $\tau_c\Delta$ indicates that the random frequency modulation is quasi-static (that is, that $\phi(t)$ relaxes in a time τ_r much shorter than the characteristic time τ_c of the modulation), so that the $\nu_s(\text{XH})$ absorption band is nearly gaussian in shape. The spectacular increase in halfwidth on freezing can be entirely attributed to a decrease in the kurtosis of the spectrum on entering the slow modulation regime.

On further cooling to 6 K the $\nu_s(\text{XH})$ band remains gaussian in profile and the halfwidth decreases to 190 cm^{-1} ; the amplitude of modulation at 6 K is estimated by analysis of the spectrum to be 81 cm^{-1} . Although this is significantly greater

150	92.9	7.0	3.9	1.50
6	80.6	8.0	5.0	1.00

The figures in the last two columns assume that α_2 is known, and are subject to possible systematic error.

Fig. 2 A comparison of the $\nu_s(\text{XH})$ absorption spectra at 170 K (liquid) (a) and 150 K (solid) (b). The halfwidths are 175 cm^{-1} and 210 cm^{-1} , respectively, but the amplitudes of modulation are 95 and 93 cm^{-1} . The spectrum of the solid solution is very nearly gaussian in profile. The feature at $3,130\text{ cm}^{-1}$ is an uncompensated solvent band, which is narrower and more prominent in the solid. The curves have been offset for display.

than the 95% confidence estimate $58 \pm 6\text{ cm}^{-1}$ obtained by extrapolating to zero temperature the relationship

$$\Delta = a + b[\coth(\hbar\omega_2/2kT)]^{1/2} \quad (5)$$

with parameters $a = (-4 \pm 10)\text{ cm}^{-1}$ and $b = (62 \pm 6)\text{ cm}^{-1}$ determined from measurements on the liquid between 160 K and 280 K, at least part of the discrepancy may be due to error in ω_2 . At 6 K the random frequency modulation of the $\nu_s(\text{XH})$ band is largely produced by the zero-point motion of the $\nu_s(\text{XH}\cdots\text{Y})$ mode.

Very similar results, consistent with equations (3) and (5), have been obtained by analysing the spectrum of a 0.2 M solution of CH_3OD in freon 11 over the same temperature range. The ratio $b(\text{H})/b(\text{D})$ (see equation (5)) is found to be approximately $\sqrt{2}$, in agreement with theory. However, the transmission window (or 'Evans hole') at about $2,460\text{ cm}^{-1}$ in the spectrum of self-associated CH_3OD complicates the analysis and leads to various uncertainties.

We believe that we have observed an unusual phenomenon: the zero-point motion of a heavily overdamped stochastic oscillator. Because of the strong damping and consequent slow relaxation of the r_2 coordinate in the frozen medium, the $\nu_s(\text{XH})$ transition dipole moment relaxes in a time which is small compared with τ_0 . The $\nu_s(\text{XH})$ band thus reflects only the probability distribution of the r_2 displacement coordinate, which is gaussian. The halfwidth of the band at liquid helium temperature is consistent with the variance of this displacement coordinate being $\hbar/2m_2\omega_2$. It must be admitted, of course, that the theory in its present form^{2,3} is semi-classical, and not strictly valid at liquid helium temperatures. The theory could be made rigorous by simply replacing the classical Ornstein-Uhlenbeck autocorrelation function $\psi(t)$ in equation (2) by an autocorrelation function derived from a quantum-mechanical model of a brownian oscillator⁹. Because in the disordered solid phase the conditions for slow modulation are well satisfied, so that the bandshape depends only on the probability distribution and not on the dynamics of the modulation process, there seems little to be gained by such a refinement.

The broad $\nu_s(\text{XH})$ bands of solutions of hydrogen-bonded species at low temperatures have sometimes been interpreted in terms of frozen-in disorder. Our work suggests that in dilute

solid solution this disorder should not be understood as a distribution of $\text{XH}\cdots\text{Y}$ equilibrium distances, but rather in terms of the slow relaxation of the r_2 coordinate back to its equilibrium position and the absence of any oscillatory character to its motion (see refs 1, 7). If there were a distribution of $\text{XH}\cdots\text{Y}$ bondlengths in dilute solid solution, it is improbable that this distribution would be gaussian or that it would produce a broadening of the $\nu_s(\text{XH})$ band at liquid helium temperature consistent with equation (3). Perhaps the most convincing evidence in favour of our interpretation, however, is the absence of any discontinuity in the amplitude of modulation at the freezing point, despite the pronounced change in the shape of the absorption band.

We thank the CEA, CIES, and CSIR for financial support, and Dr H. R. Zelsmann for assistance. G.N.R. thanks Dr Y. Maréchal for his hospitality, and discussions.

Origin of olivine subgrain boundaries in mantle peridotites

INVESTIGATION of the fabric, texture and dislocation microstructure of olivine has given much insight into the deformation history of mantle peridotites¹. Optically visible (100) subgrain boundaries (tilt or kink-band boundaries) are particularly significant in this respect. Their existence is the principal argument favouring intracrystalline glide as the mechanism of deformation² and the spacing between them (d_{100}) is considered to be a measure of the stress conditions during deformation³⁻⁶. Previous workers have argued that the sub-boundaries in olivine originated at the onset of deformation of peridotites^{1,2}, pre-dating both the recrystallised strain-free secondary grains⁷ and grain boundary development in general¹. However, re-examination of the distribution of sub-boundaries in olivine reveals features which are quite inconsistent with this interpretation. It is suggested in the present work that (100) sub-boundaries are a late feature in these peridotites and most probably have no connection with hypothetical asthenosphere flow.

The slip system activated during the development of (100) subgrains in olivine is $\{0kl\} [100]$ (ref. 8); the slip plane is usually subparallel to (010) and the slip direction is always $[100]$ (Fig. 1). Detailed thin section examination of mantle peridotites shows that the point of inside termination of a (100) sub-boundary (the point nearest to the common rotation axis of the two related subgrains; I intersection in Fig. 1) commonly coincides with a local convex feature on the grain boundary (Figs 2 and 3). The latter may be the corner of a polygonal or cusp-like re-entrant of the deformed grain or the point of maximum curvature of a smooth curvilinear boundary.

Fig. 1 Development of (100) subgrain boundaries in olivine by intracrystalline glide. (010), Glide plane; [100], glide direction; broken lines, original rectangular grain outline; σ_1 principal stress axis; I, subgrain and grain boundary intersection nearest to common rotation axis of two related subgrains.

The intersection of subgrain and grain boundaries at triple points, with reported 120° dihedral angles has been noted previously², and used as evidence for subgrain boundary development after (100) sub-boundary formation. Textural evidence contradicting this position is as follows. (1) Most olivine grains in peridotites have curvilinear to sinuous grain boundaries and re-entrants are just as cusped on grain boundaries parallel to sub-boundaries as on grain boundaries normal to sub-boundaries. 'Dihedral angles' are not in any way exclusively or even predominantly associated with the intersection of subgrain and grain boundaries. (2) The actual dihedral angles vary markedly in magnitude and show no indication of having adjusted, through recrystallisation, to equilibrium values. (3) Cusp-like re-entrants at triple points are predominantly associated with I intersections (Fig. 1) whereas re-equilibration of grain boundary energy through recrystallisation must result in a nearly equitable distribution between triple points associated with both I and O intersections (Fig. 1). (4) (100) Sub-boundaries frequently have uneven spatial distribution within individual grains, which, in itself, strongly suggests that they are localised by the convex features on the grain boundaries. (5) Sub-boundaries in primary (large) olivine grains also intersect convex features on secondary grain boundaries, and, although they are discontinuous in largely or wholly enclosed secondary grains, they do not have continuity across them. Hence, secondary olivine grains also seem to predate sub-boundary development.

Further evidence for the late development of sub-boundaries is suggested by their abundance in the elongated olivine grains of foliated porphyroclastic and equigranular peridotites⁷. The stress system required for (100) subgrain formation (Fig. 1) and the resulting deformation, shortening parallel to [100], are entirely inconsistent with the proposed deformation mode of these peridotites, translation gliding on $\{0kl\}$ [100] (refs 1, 2, 9). An attempted explanation of this inconsistency in the literature² is quite unconvincing, since the net elongation of the olivine grain under consideration is due to grain rotation, not subgrain formation. Moreover, olivine grains in these peridotites would continue to elongate with continued deformation, so that early formed sub-boundaries should become smeared and irregular. In fact, as is well known, (100) sub-boundaries are usually sharply defined and linear.

Fig. 2 (100) Sub-boundary in peridotite (spinel lherzolite) nodule from Camperdown, Victoria, Australia. Unshaded grains, olivine; shaded grains, orthopyroxene; I, I intersection (Fig. 1).

I suggest that the sub-boundaries in olivine grains of mantle peridotites developed during a later phase of deformation than that which produced the overall rock fabric. As presently envisaged, this later deformation was most probably associated with structural disruption leading to inclusion of the peridotite xenoliths in the basalt liquids. The sub-boundaries are nucleated at the convex features of appropriately orientated grain boundaries, their development being activated by the local stress concentration expected at these points. The role of stress concentration at the tip of Griffiths cracks in the brittle fracture of solids is well understood¹⁰. A direct analogy with the development of (100) sub-boundaries is the nucleation of annealing twins in face centred cubic metals¹¹. The distribution of sub-boundaries in a peridotite does not reflect the overall stress on the rock, but the local stress on individual grains. Hence, the preferred orientation of sub-boundaries in foliated peridotites is inherited from the preferred orientation of the olivine grains themselves. In undeformed peridotites the sub-boundaries are randomly orientated. The lack (or minimal development) of (100) sub-boundaries in secondary olivine grains is attributed to their smaller size and more regular and equidimensional shape, which allows them to resist deformation by subgrain formation much more readily than the larger, more irregular and highly crenulated primary grains. Similarly, partly or wholly included secondary grains appear passive to the deformation not because they postdate it but because they are inappropriately orientated to allow translation gliding on the same system as the host.

Fig. 3 (100) Sub-boundaries in Camperdown spinel lherzolite (see Fig. 2).

Recent d_{100} calculations of the stresses under which mantle peridotites have been deformed give values about one order of magnitude greater than that derived from plate tectonic models on the rheology of the mantle^{5,6}. This discrepancy has led to the suggestion that the deformation causing subgrain development occurred during diapiric upwelling of the peridotite rather than during horizontal asthenospheric flow⁵. This is essentially consistent with the present report, although the possible deformation mechanism is not necessarily limited to diapiric upwelling. Grain boundary stresses developed immediately before magma incorporation might be sufficient for subgrain development. Should this be the case, the presence of (100) sub-boundaries would not be a useful criterion to distinguish between exotic and cognate xenoliths¹². Quite clearly, the crystallisation and deformation histories of peridotites preserved as

nodules in basalts are far more complex than had been anticipated in the not-too-distant past, and the extent of preservation of asthenospheric flow characteristics in them, if indeed such ever existed, remains to be demonstrated.

I thank N. D. MacRae for rock specimens. This study was supported by the NRC of Canada.

Some new measurements on Stonehenge

THE possible astronomical significance of Stonehenge has made it desirable to make new measurements of some of its features, and I report here the results of a survey made in April 1978. New values are given for the axis of symmetry of the Avenue, the figure of the four Stations, the original position of the peak of the Heel Stone and the axis of symmetry of the sarsen trilithons (Fig. 1).

Linear measurements were taken to the nearest 5 mm with a Fibron glass-fibre tape at constant tension, calibrated against a steel tape kept as a standard. Angular measurements were made with a theodolite reading directly to 20" and by estimation to 5". The coordinate system used (Tables 1-3) has an origin 141.42 m south-west of the bronze peg β close to the centre of Stonehenge¹, with axes directed to true north and east, so that the coordinates of this peg are 100.00 E, 100.00 N. This system of local coordinates is to be preferred to National Grid coordinates, because it allows direct conversion to true azimuths. Heights are given in metres above Ordnance Datum, the level of the bench mark on stone 16 being taken as 103.11 above OD. The full National Grid coordinates of the peg β are SU 12247.43, 42195.20 (ref. 1). The referring object at the peg β was the west side of a prominent square brick chimney at Larkhill (National Grid reference 12750, 44530), the azimuth of which had been determined by Thom in 1973 as 12°10'24" (personal communication).

The part of the Avenue surveyed was the straight section which runs downhill northeastwards from the entrance of the Stonehenge earthwork. Its length to the point where it begins to change direction eastwards is 509 m. Eighteen transverse profiles were measured with a staff and level to find the lowest point of the surface over the ditch on either side, and a peg was inserted halfway between each of these pairs of points. The first of these profiles was about 2 m from the beginning of the Avenue and the last about 16 m from the end of the straight section. The remainder were spaced about 30 m apart, except where the modern road (A 344) crosses the Avenue. The coordinates of the index-marks on the pegs were then determined by a theodolite traverse. The closing error over a distance of 982 m was 0.087 m, giving a consistency of measurement of better than 1 part in 10,000. The adjusted coordinates of the 18 pegs A-T are shown in Table 1. The traverse began and ended at peg A.

Regardless of the method adopted for estimating the azimuth of the straight line which is the 'best fit' to these 18 points, the

result is extremely close to 49°54'40", and this is accordingly taken to be the azimuth of the axis of symmetry of the straight section of the Avenue. This value has been confirmed by direct observations of the azimuths of the lines joining the ends of the two Avenue ditches. At the Stonehenge end these were excavated by Hawley in 1923 (ref. 2), and were located by probing for the lowest point of the ditch bottoms in 1978. At the far end, where the Avenue begins to change direction, both ditches were exposed by excavation in 1978. The azimuth of the north-west ditch, end to end, is 49°52'19", and that of the south-east ditch 49°56'5", both values being the mean of six observations. The mean of these two values, 49°54'12", agrees well with the calculated axis.

This new value differs significantly from the mean axis of 49°35'51" found by Lockyer³, and from the axis of 49°34'18" which he adopted for reasons which can now be seen to be irrelevant. Lockyer used only six pegs on the apparent centre line of the Avenue, and did not record their positions in detail. Two of them were 140 ft apart "near the commencement of the avenue", and four others "at distances averaging 100 feet apart nearer the further recognisable extremity". Elsewhere, he states that the Avenue was discernible "for more than 1,300 ft from the centre of the temple". This implies that his furthest peg lay not more than 425 m from the centre of Stonehenge. The straight section of the Avenue continues, however, for a further 139 m beyond this point, although it has been somewhat reduced by cultivation.

It is no longer necessary to attempt to derive the date of construction of this section of the Avenue from its orientation, as Lockyer did, because there are now two closely agreeing radiocarbon dates from deer antler picks found on the bottoms of the two ditches close to Stonehenge. These are BM-1164, 1728±68 b.c. and HAR-2013, 1770±70 b.c. The weighted mean of these dates, when corrected⁴, is 1265±80 b.c.. At this date the first gleam of the summer solstice sunrise (with 2' of the upper limb above the horizon) would have had an azimuth of 49°30', which differs from the axis now determined by about 25'

Fig. 1 Diagrammatic plan of Stonehenge, showing the beginning of the Avenue, the Heel Stone, the four Stations (91-94), the sarsen circle and horseshoe, and the survey point β . Standing stones are shown in black, fallen and missing stones in outline.

Q	448.61	394.88	91.31
R	471.65	413.80	90.96
S	494.41	433.04	90.53
T	519.00	453.54	89.60

If, however, there were trees growing on the skyline to a height of 10 m, which is by no means impossible, the azimuth of the apparent sunrise thus defined would have almost precisely matched the azimuth of the axis now determined.

If it is assumed that the lines of the Avenue ditches were laid out by lateral offsets from a central axis, and that this axis passed through the point defined by the means of the coordinates of the points A–T, then the axis prolonged southwards would have passed 1.46 m north of the peg β , 1.14 m north of the centre of the sarsen circle and 1.74 m north of the centre of the Aubrey Holes¹. The centre of the unfinished double circle of bluestones of period II (ref. 5) is not known precisely, because only a small proportion of its stoneholes have so far been excavated; however, the available evidence suggests that it was close to the centre of the subsequent sarsen circle. These divergencies imply, therefore, that the double bluestone circle and the Avenue, both of period II, did not share a common axis of symmetry.

The four Stations lie approximately on the circumference of the circle of Aubrey Holes, and are often stated to have formed a rectangle with sides aligned on extreme azimuths of the rising of the Sun and Moon⁶. Until the present survey, however, the position of Station 94 was located only by inference or conjecture. The values given here (Tables 2 and 3) are derived from direct observation and measurement on the ground.

Station 91 is represented by a fallen stone, now leaning outwards against the inner slope of the bank, with an overall length of 2.75 m. The original position of its centre is best estimated from the outline of the steep-sided stonehole in which it stood. This was found by probing in April 1978.

At Station 92, the centre of the deepest part of the stonehole can be determined from an unpublished plan made after its excavation in 1921 (ref. 7), and was confirmed by probing in July 1973 and again in April 1978.

Station 93 is occupied by the stump of an upright stone, but the dressing of parts of its sides below present ground level (and well below prehistoric ground level), like that of the sarsen stones of period IIIa, suggests that it may be a later replacement of an earlier marker. The other surviving Station stone, no. 91, shows no signs of dressing on its visible surface. The centre of stone 93 was determined by direct measurement.

The stonehole at Station 94 was located by excavation for the first time in April 1978, when the gravel access-path beneath which it lies was being replaced by turf. The filling was removed only far enough to define the upper edge of the hole, at the surface of the chalk, but probing showed that the sides descended almost vertically. Its eastern margin, where it may overlap

the adjacent Aubrey Hole 46, was left undisturbed. This Aubrey Hole was probably excavated, in part at least, by William Cunnington on behalf of Sir Richard Colt Hoare early in the nineteenth century. The latter records the finding of a cremated human burial⁸, many of which have been found in the other excavated Aubrey Holes⁹.

The coordinates of the apparent centres of the four Stations, the included angles at each, and the lengths and azimuths of the sides of the quadrilateral thus defined are given in Tables 2 and 3. These values suggest that the figure of the four Stations could have been intended to be a rectangle, with adjacent sides and diagonals roughly in the ratio of 5:12:13, the Pythagorean triangle suggested by Dibble¹⁰. From the evidence available, however, it is impossible to determine the precise shape, size or orientation of the original figure, because it cannot be assumed that the peaks of the stones (the points of reference for astronomical observations) were identical in plan with the centroids of the holes in which they stood. For this reason the original azimuths may have differed from those given here by at least $\pm 1^\circ$ for the shorter sides of the figure, and by at least $\pm 30'$ for the longer. These uncertainties must be taken into account in any calculation which is made with the aim of showing that the four Stations had an astronomical significance.

The Heel Stone now leans very markedly from the vertical, although this has sometimes been ignored in discussing its astronomical significance¹¹. By a combination of direct measurement and photogrammetry, its inclination has been determined as $24^\circ 26'$ from the vertical, in a plane bearing $233^\circ 22'$ from true north. The coordinates of its peak, as seen today from the centre of Stonehenge (peg β) are 160.21° E, 148.75° N, 105.07 m above OD. If it were set vertical, its present apparent peak would lie a little beyond and below its new apparent peak, the coordinates of which would be 161.94° E, 150.04° N, 105.60 m above OD.

The Heel Stone is part of the structure of period I, for which the best estimate of the centre is that of the circle of Aubrey Holes (Table 1). The ground levels within the stones of Stonehenge have been altered during the last 25 yr by re-turfing, by the laying of gravel in 1963 and by its replacement with turf in 1978; but extrapolation from adjacent contours on undisturbed ground suggests that in the absence of disturbance the ground level at the Aubrey centre would today be 102.38 m above OD. If an allowance of 0.56 m is made for the weathering of the chalk since the building of Stonehenge I (ref. 12), and of 1.55 m for the eye-height of a prehistoric observer¹³, the level of a prehistoric observer's eye would have been at 104.49 m above OD. From this position the azimuth of the peak of the upright Heel Stone would have been $50^\circ 54'$, and its altitude would have been $47^\circ 29'$, so that 0.3 m of its top would have projected above the bare horizon. Once more, however, if there were trees on the skyline standing more than 10 m high, the peak of the stone would not have projected above the apparent horizon for an

Table 2 Coordinates and included angles at the four Stations

Station	Eastings	Northings	Included angle
91	139.00	80.00	$89^\circ 24'.6$
92	113.03	57.80	$89^\circ 32'.5$
93	61.58	118.97	$91^\circ 2'.4$
94	86.22	140.47	$90^\circ 0'.5$
Intersection of diagonals	99.37	99.99	$45^\circ 11'.4$

Table 3 Distances and azimuths between the stations

Stations	Distance	Azimuth
91 to 92	34.17	$229^\circ 28'.5$
92 to 93	79.93	$319^\circ 56'.0$
93 to 94	32.70	$48^\circ 53'.6$
94 to 91	80.26	$138^\circ 53'.1$

observer of the summer solstice sunrise. A question posed by Hoyle thus remains unanswered¹⁴.

Thom has shown¹ that the inner faces of the outer four trilithons at ground level are a good fit to an ellipse, the major axis of which has an azimuth of $49^{\circ}57' \pm 3'$, corresponding to astronomical sunrise at 1600 ± 450 b.c. He recognised that the second, or south, trilithon (stones 53, 54) was leaning inwards, perhaps by 3° at ground level, but even so, his estimate of the axis of symmetry of the trilithons was based on the present ground plan of their inner faces.

The inclination of the second trilithon was estimated in the present survey to be $1^{\circ}5'$ from the vertical, which corresponds to an inward displacement at ground level of 0.10 m. If this is corrected, the major axis of the best-fit ellipse would be rotated anticlockwise through an angle of $25^{\circ}-30^{\circ}$, giving a revised azimuth of about $49^{\circ}30'$. This is close to the calculated azimuth of the first-gleam summer solstice sunrise (with $2'$ of the upper limb showing) in 2045 b.c., which is $49^{\circ}31'17''$. This date is the weighted mean, when corrected, of two radiocarbon dates for the Stonehenge II/IIIa transition, BM-46, 1720 ± 150 b.c. and I-2384, 1620 ± 110 b.c. The resulting inference is that the bull-dozers of the Avenue and of the sarsen structure defined sunrise by the first gleam of the upper limb of the Sun over the apparent horizon.

I thank the National Trust and their tenant, Mr J. Wort, for permission to survey and excavate on the Avenue, the Ancient Monuments Directorate, Department of the Environment, for permission and facilities for the excavation at Station 94, the Department of Civil Engineering, University College, Cardiff for the loan of a theodolite, and my wife for much patient help.

Determination of critical variables in a microbial predator-prey system by catastrophe theory

THE differential or difference equations that are used customarily to describe predator-prey interactions can give many insights into the behaviour of simple ecosystems, but only rarely can they be used to predict the population densities of real organisms with any accuracy. Thus even given long-term observations of population densities it is often difficult to deduce very much about the behaviour of the organisms. We present here an analysis in which we use population measurements to determine the variables that govern the response of an amoebal predator to its prey. Our results support the suggestion of Curds and Cockburn¹ that it is the prey-predator ratio rather than the prey density to which the amoebae are sensitive. We have arrived at our conclusions by applying catastrophe theory² in a way that we believe will be useful in many other contexts.

Dent *et al.*³ grew vegetative amoebae of the cellular slime mould, *Dictyostelium discoideum*, in continuous culture with a bacterial food source, *Escherichia coli* B/r. Figure 1 illustrates

Fig. 1 Biovolume density of *D. discoideum*, data from ref. 3. The solid line is the fit obtained using the cusp catastrophe and is not significantly sensitive to the choice between the two conventions discussed in the text.

how during the first 150 h of the experiment the amoebae passed through alternating phases of exponential growth and decline. There was a very rapid change from one such phase to the next, and the specific growth rate, λ , remained constant throughout intervals of as much as a day, during which time the bacterial concentration measured in terms of biovolume (the product of the number density and the mean cell volume) could change by a factor of 100. The observation that the specific growth rate was shifting abruptly from one more or less constant value to another rather than moving smoothly in response to changes in prey density suggested that the system could profitably be studied in terms of catastrophe theory with λ as a state variable.

From Thom's list of seven elementary catastrophes we chose the cusp because it is the simplest which is consistent with the observation that in time the sudden changes in λ became smaller and eventually disappeared altogether. The cusp catastrophe requires two control variables, and we chose the culture age (a) and the bacterial biovolume density (H). With these choices a plot of prey biovolume as a function of time becomes the projection of the trajectory of the system into the control space (by system we mean the biochemical reactions which determine the behaviour of the amoebae, not the predator-prey system as a whole). By marking the points at which the abrupt changes in the state variable occurred, we were able to sketch the catastrophe set (Fig. 2). We could then relate a and H to the control variables of the canonical cusp catastrophe, and this in turn reduced the determination of λ as a function of a and H to a simple curve-fitting exercise. We then integrated λ to obtain the solid curve drawn in Fig. 1.

The curve clearly fits the data well, though we stress that the significant point is the qualitative picture, that is the nearly straight lines and the decreasing periods and slopes. The close agreement between the observed and predicted numerical values of the slopes is not evidence in favour of the model, because catastrophe theory allows us sufficient freedom to arrange this agreement providing that the qualitative behaviour is correct.

There is, however, a difficulty. Catastrophe theory explains sudden jumps in terms of shifts of the system from one stable equilibrium to another⁴. To predict where these will occur we must know not only how many stable steady states exist at a given point in the control space but also what determines which of two or more alternative steady states the system will be in. The former is deduced from the canonical form as given by Thom² and the latter is determined by specifying one of the 'conventions' of catastrophe theory. The two commonly used

conventions are the 'perfect delay' convention, in which we suppose that the system will remain in a local minimum until that minimum disappears, and the 'Maxwell' convention, in which we suppose that the system will always seek a global minimum of potential.

The catastrophe set indicated by the broken lines in Fig. 2 has the familiar cusp shape characteristic of the perfect delay convention, but the jumps occur as the trajectory enters the cusp, not as it leaves it. This implies that the system is moving away from one stable equilibrium and towards another at a higher potential. Such behaviour is not impossible to explain, but it involves a rather complicated mechanism as the system requires some separate means for choosing between steady states (P.T.S. in preparation).

We have found, however, that if we replace the control variable H by H/P , the ratio of prey to predator biovolume densities, we obtain the result shown in Fig. 3. All five jumps now lie on a single straight line, which we take as the catastrophe set of the cusp catastrophe with the Maxwell convention. This convention does not require us to postulate a separate switch, and so we deduce that the factor which determines the growth of the amoebae is more likely to be the ratio of biovolumes. This is contrary to what is assumed in most models of microbial predation but is supported by the result of Curds and Cockburn¹ who found that the feeding rate of *Tetrahymena pyriformis* was more closely correlated with H/P than with H .

We have a predator-prey system which we have not been able to model in detail and which has features inconsistent with the usual models. As a first step towards understanding the system, we want to know whether it is H or H/P to which the amoebae respond. Catastrophe theory tells us that if the critical variable is H/P , then a comparatively simple mechanism can account for the observed behaviour. If, however, the critical variable is the prey density H , then the mechanism will have to be much more complicated with, in effect, two separate switches to control a single response. We conclude that H/P is far more likely to be the correct choice.

The curves in Figs 2 and 3 were obtained by fitting cubic splines to the data of Dent *et al.*³ and we must ask how sensitive our results are to small variations in the shapes of these curves. It is clear that in Fig. 2 no minor change in the curves nor difference of an hour or two in the location of the peaks and troughs of amoebal biovolume can alter the configuration of the jumps. The catastrophe set will remain qualitatively the same and neither the Maxwell nor perfect delay conventions will be

Fig. 3 The same as Fig. 2 but with prey-predator ratio as ordinate.

applicable. In the case of Fig. 3, however, we cannot rule out the possibility that the dynamic follows the perfect delay convention with a very narrow cusp. This would matter if we were trying to guess the actual mechanism, but it does not affect our argument concerning the relative simplicity of the possible mechanisms. Our conclusions thus do not depend on the precise shape of the curves.

If, as we believe, the rate of growth of amoebae is controlled by H/P , there must be some mechanism by which the amoebae can estimate this ratio. It has been suggested² that folic acid, which is secreted by *E. coli* (and by soil bacteria as well) may serve as an attractant for food-seeking amoebae. If folic acid molecules are modified on contact with amoebal receptor sites, then the concentration will depend on the ratio of prey to predator densities. We are doing experiments to determine whether the folic acid concentration governs the behaviour of the amoebae.

We disagree with Zahler and Sussman⁴ that "catastrophe theory is a blind alley". By applying it we have discovered what seem to be the correct critical variables in our system. The theory made us concentrate on the amoebal specific growth rate, and ask how this could be affected. The need for two control variables led us to consider culture age as an explicit variable, even though most equations used in population dynamics are autonomous. This provided a link between the early stage of the experiment described here and the observation² that after about 200 h there is an apparently spontaneous change in the population densities of both organisms. Finally, catastrophe theory has provided strong evidence that it is the ratio of biovolume densities to which the amoebae respond, and this has suggested further experiments.

We expect that the way in which we have used catastrophe theory to decide between alternative choices of critical variables will find other applications in the study of complex systems. It does not require data as accurate as would be necessary to fit a model based on differential equations. It requires no definite hypothesis concerning the mechanism of the system and it leads to conclusions that are comparatively robust, for they do not stand or fall with one particular choice of mechanism or *ad hoc* equation. We do not claim that we are somehow obtaining more information from our analysis than was contained in the data—no mathematical technique can accomplish this. What catastrophe theory can do, however, is enable us to answer a limited number of questions about a system on the basis of much less information than would be needed for a complete description. Much of the power of the theory lies in the fact that this limited

Fig. 2 Biovolume density of *E. coli*, with the catastrophe set indicated. The points at which the sudden changes in λ occurred are marked by solid circles. Data are based on ref. 3.

number of questions so often turns out to include the most interesting ones.

Asynchronous sexual development determines the breeding system in field beans

THE breeding system of varieties of field bean (*Vicia faba* minor L.) has long been known to be intermediate between allogamy and autogamy, with approximately 1/3 of the seeds set as a result of cross-fertilisation and 2/3 by self-fertilisation¹. Cross-fertilisation is due to bees visiting open flowers. Most inbred lines show poor seed set unless their flowers are visited by bees or artificially manipulated (tripped) and are therefore called autosterile; a few lines which do not require tripping are called autofertile^{2–3}. Irrespective of variety, so far as is known, the field bean does not possess a self-incompatibility system for regulating fertilisation^{4–6}; also anther dehiscence always precedes flower opening by one or two days. Why then does the temporal advantage of self pollen over cross pollen not lead to obligate autogamy under field conditions? In an attempt to answer this question, it has been suggested that a spatial separation between discharged pollen and the stigma is normally present, but is abolished by bee visits which simultaneously bring about pollen–stigma contact and chance cross-pollination. According to this hypothesis, autosterile lines have a serious impediment to pollen–stigma contact, whereas, due to a different floral architecture, autofertile lines do not⁷, although intermediate floral structures also occur. Here we report results of a scanning electron microscopic (SEM) study of the stigmas of an autosterile line (T2) and an autofertile line (T51), which lead to an alternative explanation for autosterility and autofertility.

After freezing open flowers in vapourised liquid nitrogen at –110 °C the petals were removed without causing disturbance to the stigma region. Flowers of the autosterile line T2 examined

Fig. 1 Scanning electron micrographs of uncoated *Vicia faba* stigmas at 7.5 kV × 160. *a*, Line T2 after flower opening stage showing stigma surface covered with pollen grains: flower frozen in vapourised liquid nitrogen and dissected without stigma disturbance. *b*, Line T2 emasculated before anther dehiscence showing exudate on stigma surface 18 h after treatment (c.f. Fig. 2*d*, 2*e* for controls).

Fig. 2 Scanning electron micrographs of uncoated *Vicia faba* stigmas taken at 7.5 kV × 160, showing exudate appearance during flower development of line T51 (*a–c*) and line T2 (*d–f*). Flowers were taken from the 4th to 8th flowering node at comparable developmental stages: before anther dehiscence (*a*, *d*); after anther dehiscence but before flower opening (*b*, *e*); after flower opening (*c*, *f*).

in this way were found always to have stigmas covered with pollen grains (Fig. 1*a*), showing that autosterility is not due to a spatial separation of stigma and self pollen grains in the undisturbed flowers. Autofertile lines also showed abundant pollen. Stigma surfaces were then examined by SEM after ungerminated pollen grains had been removed from the stigma surfaces by briefly rinsing in distilled water. This investigation showed differences between lines T2 and T51 with regard to the amount and time of appearance of exudate on the receptive areas of the stigma tip (Fig. 2*a–f*). In the autofertile line T51, exudate was present before anther dehiscence (Fig. 2*a*). After dehiscence but before flower opening, self pollen was seen entrapped in an increased quantity of exudate (Fig. 2*b*). Even more exudate was apparent on the stigmas after the flowers opened (Fig. 2*c*). In the autosterile line T2, however, there was no exudate before anther dehiscence (Fig. 2*d*) or before flower opening (Fig. 2*e*), although small amounts of exudate were found on stigmas from open flowers (Fig. 2*f*).

In angiosperm species, including *Vicia faba*, in which a wet stigma is characteristic, it has been suggested that stigma receptivity is signalled by an accumulation of exudate on the stigma surface⁸. In autofertile line T51 and in some other lines (data not shown) where exudate appears and anthers dehiscence before flower opening, the probability of self-fertilisation might be expected to increase. This has been found to be so in at least one instance, where under field conditions⁹ an autofertile line showed much lower outcrossing than did corresponding autosterile lines.

In artificial field bean pollination, manual tripping of open flowers is a recommended practice for increasing seed set in autosterile lines¹⁰. Consequently, we examined the influence of tripping and emasculating on exudation and found, as expected, increased stigma exudate after both treatments (see Fig. 1*b*).

On the basis of these findings the so-called autofertile lines can be classified as protogynous and autosterile lines as protandrous. It seems that the timing of stigma receptivity, as manifested by exudation, acts as a critical control in field bean

pollination. This role of the stigma in actively regulating the breeding system may possibly apply to other bee-pollinated papilionaceous species.

We thank Gillian Toynbee-Clarke and Dr D. Bond (the Plant Breeding Institute, Cambridge) for seed material. C. P. acknowledges financial support from Deutsche Forschungsgemeinschaft and P. Gates is in receipt of a SRC postgraduate studentship.

Does colour provide an input to human motion perception?

A PUZZLING feature of the visual system of primates is the occurrence of a multiplicity of separate 'maps' of the visual environment, each of which has its own independent set of afferent connections. Perhaps these maps represent an early stage in the analysis of visual information by the brain. Electrophysiological studies have shown that depth is analysed in V_2 (area 18) (ref. 1), that colour-coded cells occur mainly in V_4 and that motion in the visual field is analysed in the posterior bank of the superior temporal sulcus² (Fig. 1). We report here an experiment which suggests that colour and movement are handled separately in the visual system and that information defined by wavelength cannot be processed by the brain's motion-detecting mechanisms. This finding is consistent with Zeki's demonstration that "cells of the movement area are not concerned with colour"^{2,3}.

Stimuli used were based on Julesz' random-dot stereograms⁴ (Fig. 2). The members of the pair of random-dot arrays are identical except that all the dots of a central square-shaped region are horizontally shifted to an equal extent in one display in relation to the other. On monocular inspection, only random dots are seen for either display, but when fused binocularly, the central shifted region stands out in depth from the rest of the dots, as a square having a sharp border; this may be described as an illusory contour, as it is not defined by the (irregular) dots of the displaced region.

Lu and Fender⁵ found that when such a display is presented with coloured dots against a contrasting colour background, stereoscopic depth is lost when the dots and the background have equal luminance, although the dots are clearly seen by colour contrast at isoluminance.

The use of random-dot stereograms has not been limited to stereoscopic experiments. In the present experiment, random-dot displays are not presented to give stereoscopic depth; they are optically superimposed, and are exposed alternately at a rate which gives apparent motion of the central displaced region, which then appears as a square oscillating horizontally^{4,6}. The square has (very much as for stereoscopic presentation) a clearly defined illusory border. Neither the border nor the motion are visible without alternation of the pair of dot displays. The

Fig. 1 The lower diagram shows a horizontal section of the brain of a rhesus monkey taken at the level indicated in the upper diagram to show regions of the prefrontal cortex that are specialised for colour (marked by crosses) and motion (stippled) (adapted from Zeki²).

appearance of the border can be used as an independent and unambiguous criterion of motion perception⁷.

We used these patterns to study the role of colour as an input to human motion perception. Each dot in the original pattern (Fig. 2) is defined by a stepwise change in intensity (that is, black dots on a white background). Our strategy was to convert these intensity gradients into gradients of 'pure' wavelength; that is, we replaced all black-white borders with red-green borders using an isoluminance projection system⁸. The intensity of the green areas was then varied continuously over a wide range so that at least at some setting the intensities of red and green must have been precisely matched.

Isoluminance, with exact registration of the colour areas to prevent brightness contours, was obtained by projecting a special colour transparency with combined epi and dia projection through a single lens⁸. Two light sources were independently controlled for intensity, the epi source, which illuminates the upper coloured (red) surface of the opaque regions of the transparency, and the dia source, which projects by means of a colour filter (green) through the transparent regions. The transparency may be photographically produced silk screen prints; or 3M colour-key contact imaging material (red opaque negative), as used here. The format was 60 mm².

An identical pair of these projectors allowed a Julesz pair of transparencies to be superimposed, and projected alternately with a pair of electrically synchronised rotating sector-disk shutters. 'Key-stoning' distortion was avoided by placing one projector behind and the other in front of a translucent screen.

Fig. 2 A Julesz random-dot stereogram (see text for explanation). The two patterns were optically superimposed and exposed alternately to produce apparent motion.

The projected display was 37 cm² viewed from about 1 m, subtending 65°. The dot elements were 2 cm, subtending 3°, which was at least two orders above visual resolution at isoluminance. The screen luminance at isoluminance match was about 0.34 cd m⁻². Similar results were obtained at higher intensities (up to 34 cd m⁻²).

Four volunteers were used and two of them were unaware of the purpose of the experiment. Each subject began by deliberately introducing a large brightness difference between the red and green areas. At a frequency of about 100; 50; 100 (stimulus duration 100 ms; interstimulus interval or ISI 50 ms), a square with well-defined edges could be seen oscillating back and forth horizontally. Using the luminance control knob the intensity of the green dots was then varied continuously over a wide range. The subject was asked to record what he saw as he rotated the knob.

As the green background luminance was gradually reduced from a high value to near isoluminance, all subjects reported disappearance of the square. The square then reappeared when the luminance of the green was reduced to a level below the 'isoluminance' point. The disappearance of the square was quite sudden, and reported spontaneously by all four subjects.

Table 1 Critical range of luminance of green dots for each of four subjects

Subject	Luminance range (cd m ⁻²) over which square was invisible	Luminance range (cd m ⁻²) at which motion was invisible
1	4.42	6.84
2	4.32	6.84
3	4.73	7.68
4	3.49	7.68

Each entry represents the mean value of four readings.

Table 1 shows the 'critical range' of intensities over which the square disappeared for each of the four subjects. For all subjects: (1) the square disappeared slightly earlier than motion and was completely invisible over a narrow range of about 58% which was fairly constant for each subject, (2) the luminance setting for motion disappearance was remarkably constant among subjects. At this setting, three of the subjects reported that they could still see a slight 'shimmering' but none of them could detect any motion.

Having found the critical range, we varied other parameters to see if the square could be restored. Increasing the frequency of alternation did not make any difference. On lowering the frequency to about half the original rate, some of the dot elements could be seen moving, but the direction of motion was ambiguous and the edge defining the square remained invisible. Neither the square nor unambiguous motion could be restored at any frequency. We also tried doubling or halving the size of dot elements and/or the spatial displacement of the inner square, but these proved equally ineffective.

It is important to note that at the setting at which motion disappeared, the individual dots could be discerned just as clearly as when luminance contrast was present. Conversely, even gross blurring of the pattern (by defocusing the projectors) did not destroy the square as long as brightness differences were preserved.

In a control situation we used light red-dark red dot patterns instead of red-green. The intensity of one of the reds was then varied continuously. All four subjects reported that the disappearance of the square (and of motion) coincided almost exactly with the actual disappearance of the dots at isoluminance. The critical range for the disappearance of the square and of motion was thus much narrower than that measured using red-green dots (Table 1). Thus, colour cues seem to have, if anything, a slightly detrimental effect on the perception of coherent apparent motion.

The disappearance of motion at isoluminance is exactly analogous to Lu and Fender's⁵ discovery that stereopsis disappears at isoluminance in stationary random-dot stereograms. 'Classical' stereopsis, using monocularly visible line targets, apparently does not break down completely at isoluminance⁹, and we now find that this is also true of apparent motion. If two simple line targets are alternated instead of random-dot patterns, motion does not disappear at isoluminance.

As in the case of stereopsis⁹, random-dot targets may be processed differently from simple line targets. The former must involve cooperative interactions between large populations of cells tuned to either the same disparity^{4,10,11} or even (in the case of motion detectors) the same direction and velocity. Our findings may imply that at isoluminance cooperative facilitation is not possible between colour contrast-sensitive motion detectors. Alternatively, the relevant motion detectors may be insensitive to wavelength, which is consistent with physiological evidence³, and especially with the observation that monkey colour-opponent neurones give sustained responses whereas broad-band non-opponent neurones respond transiently¹²⁻¹⁴.

Regardless of our interpretation, it is clear from our findings that colour and motion are handled separately by the human visual system and that colour provides only a weak 'cue', at best, to movement perception.

We thank Dr O. J. Braddick for providing some of the Julesz stereograms used for making the special transparencies for isoluminance projection.

Suppression of oestrogen-induced LH surges by social subordination in talapoin monkeys

It is axiomatic that the social structure of a group of primates has a pervasive effect on each individual's behaviour. Thus, many monkeys form dominance hierarchies, based on the successful outcome of aggressive interactions, and the more subordinate animals show characteristic behavioural traits^{1,2}. In particular, the social hierarchy has marked effects on reproductive behaviour, especially in talapoin monkeys, where sexual interactions tend to be the prerogative of the dominant males³. Subordinate male rhesus monkeys have limited access to sexually attractive females and produce fewer offspring⁴, and in the few species that have been carefully examined, subordinate females, although apparently receiving sexual attention, are, nevertheless, less fertile than would be expected⁵⁻⁷. Recently, it has become clear that the dominance hierarchy affects not only behaviour but also hormone levels. Testosterone is higher in dominant males^{8,9}, cortisol and prolactin are raised in more subordinate animals¹⁰. We report here evidence that subordination can prevent the luteinising hormone (LH) surge which

Table 1 Sexual and aggressive behaviour, plasma cortisol and prolactin in female talapoins

		Dominant female	Subordinate female	<i>z</i>	<i>P</i>
Total aggression received from males	Attacks	45	110	2.099	<0.02
	Threats	11	15	0.54	NS
	Displaces	8	61	3.79	<0.001
Total aggression received from females	Attacks	2	55	3.52	<0.0002
	Threats	0	11	2.28	<0.01
	Displaces	0	216	8.79	<0.0001
Sexual behaviour received	Mounts	339	64	7.31	<0.0001
	Ejaculations	139	6	7.52	<0.0001
Mean plasma prolactin ± s.d. (ng ml ⁻¹ , human standard)		61.4 ± 43.0	125 ± 55.4	<i>t</i> 8.22	<0.001
Mean plasma cortisol (µg ml ⁻¹ ± s.d.)		176.5 ± 43.1	207.6 ± 76.6	2.4	<0.02

Behaviour was based on 1,000 min of observations during five separate two-week periods when females received oestrogen. Plasma samples were collected over a 10-month period during which females received their oestrogen implants. Attack: the aggressor chases its opponent and attempts to grab and bite it. Threat: eyebrows are raised, eyes open wide and the mouth open to varying degrees. Displace: such aggression often occurs when the subordinate monkey is occupying a food hopper or sitting with another monkey. Without necessarily making contact the dominant monkey may cause the subordinate to move away and then occupy the same position. (*z*, Mann-Whitney; *t*, Student's *t*-test). NS, not significant.

is normally induced by giving oestrogen to female monkeys, thus offering an explanation for reduced fertility and suggesting that this can be induced by behavioural interactions.

A socially living group of four male and four female talapoins was studied in a large cage (11' × 8' × 5') in which they had lived for about one year before the experiments described here. Males and females were denied access to each other apart from for two periods of 50 min d⁻¹, when sexual, aggressive and social behaviour were scored quantitatively from behind a one-way vision screen as described elsewhere¹¹.

The males were intact; females were ovariectomised and were implanted with a single oestrogen-filled capsule (1.5 cm × 3.2 mm × 1.0 mm) producing plasma levels of 100–150 pg ml⁻¹, approximating those occurring in intact females during the follicular phase of the cycle. These were removed and replaced at intervals to ensure maximal sexual skin swelling and female attractiveness. The administration of an oestrogen surge to the hypothalamo-pituitary axis is a well recognised method of inducing discharge of LH in primates¹². An oestrogen surge was produced in the female talapoin by inserting two additional oestrogen-filled capsules and plasma samples were then taken at intervals over the following 5 d. Plasma oestradiol¹³, LH¹⁴ and prolactin¹⁵ were measured by radioimmunoassay and the animals' behaviour continued to be scored twice daily.

Before oestrogen surges were given, the group had been observed for about one year and plasma samples taken twice weekly. During this time, both dominant and subordinate females received the same dose of oestrogen. Both engaged in sexual interactions, although this was more frequently observed in the case of the dominant female (Table 1). Aggressive behaviour was also different, the subordinate female receiving much more than the dominant. Plasma cortisol and prolactin levels were raised in the subordinate compared to the dominant female during the time they lived together (Table 1). The dominant female when given an oestrogen surge on three occasions (each separated by approximately 21 d) always produced an LH surge about 50–70 h later; in no case was this observed in the subordinate female even though oestrogen levels were comparable to those of the dominant animal (Fig. 1). During treatment with additional oestrogen, the behavioural differences between the two females were again observed, the dominant female receiving more ejaculations (18 mounts and 15 ejaculations in 10 h observation) than the subordinate (14 mounts, 0 ejaculations in 10 h observation). No aggressive interaction was directed towards her although a considerable amount was received by the subordinate (10 attacks, 4 threats,

Fig. 1 Plasma LH and prolactin levels in dominant (a) and subordinate (b) female talapoin monkeys when given extra oestradiol (E₂) implants (indicated by arrows) over a five-day period. The subordinate female has significantly higher prolactin levels and unlike the dominant female does not respond with an LH surge

Fig. 2 Effects of suppressing or elevating prolactin on the oestrogen (indicated by large arrow) induced LH surge. The subordinate female (b) receives bromocryptine treatment by daily injection (indicated by small arrows) which lowers plasma prolactin and permits an LH surge. The LH surge is blocked when plasma prolactin is elevated by haloperidol treatment in the dominant female (a).

14 displaces). Plasma prolactin continued to be significantly higher in the subordinate female (mean $115.7 \pm 35.3 \text{ ng ml}^{-1}$) than the dominant female ($50.8 \pm 17.0 \text{ ng ml}^{-1}$), $t = 7.15$, $P < 0.0001$) during the oestrogen challenge (Fig. 1). The subordinate female was subsequently treated with a dopamine agonist, bromocryptine, a procedure which effectively lowers prolactin in humans and can restore ovulation^{16,17}. This resulted in the reduction of plasma prolactin levels, and when challenged again with two oestrogen-filled capsules during bromocryptine treatment, an LH surge occurred which resembled that formerly seen in the dominant female. Conversely, the prolactin levels in the dominant female were raised by giving her the dopamine receptor blocker, haloperidol. This both raised her prolactin level and rendered the oestrogen challenge ineffective, no additional LH being released (Fig. 2). (It is also well recognised in humans that high prolactin levels are associated with amenorrhoea and failure to ovulate¹⁶.)

As it was possible that the raised prolactin levels in the subordinate female might be due to factors other than her social environment, she was removed from the group and housed singly. Eight weeks later, her prolactin levels had fallen to those comparable with the more dominant animals, and the oestrogen challenge now induced an LH surge without the need for bromocryptine treatment.

Our results show that behavioural interactions can so alter the female primate's neuroendocrine system as to render it unlikely that she could conceive. Thus, reduced fertility observed in certain subordinate female primates in the wild, and that observed in humans during stressful situations¹⁸, could be related to the hormonal changes we describe here. We cannot be sure that the effect of the drugs on LH secretion was due to the consequent changes in prolactin, for dopamine is also implicated directly in the release of LH¹⁹. It is certainly possible that high levels of prolactin, however produced, are inhibitory to ovulation and hence fertility. Furthermore, we can speculate that the syndrome of hyperprolactinaemia in women could be induced or aggravated by behavioural mechanisms. Of course, these would not necessarily involve overt aggression as described in the talapoin monkeys, but whatever factors threaten the social stability of the individuals concerned, and the way in which they

react to this, would provide a more likely parallel for our own species. While not wishing to imply that all subordinate monkeys are necessarily infertile, such a mechanism, if it is physiologically active, may also be a way whereby subordinate females would contribute less to the breeding of a group than might be expected by simply observing their overt sexual behaviour.

This work was supported by an MRC programme grant to Joe Herbert whose help has been invaluable throughout. We thank Raith Overhill for drawing the figures, Debbie Steer for typing the manuscript, Drs Friesen (PRL antiserum) and Niswender (LH antiserum) NIAMDD (LH and PRL standards), MRC (h-PRL for iodination) for materials for radioimmunoassay, Sandoz for bromocryptine and Searle for haloperidol.

We'll be specific

Receptor-specific proteins are valuable reagents in cell studies because of their well-defined interaction specificities. You must be able to rely on them being pure, biospecific and fully active. You can when you purchase your receptor-specific proteins from Pharmacia Fine Chemicals.

		<i>Specific for:</i>
	Concanavalin A*	D-Glucose/Mannose
	Soybean Lectin	N-acetyl-D-Galactosamine
New	Lentil Lectin*	D-Glucose/Mannose
	Wheat germ Lectin*	N-acetyl-D-Glucosamine
New	Helix pomatia Lectin*	N-acetyl-D-Galactosamine
	Protein A (<i>S. aureus</i>)*	F _c region of immunoglobulin G
New	FITC-Protein A	F _c region of immunoglobulin G (fluorescent, for microscopy)

*Also available Immobilized on Sepharose®, for use in affinity chromatography.

Biospecific interaction between a receptor-specific protein and its corresponding ligand – the property important for your experiments – is the mechanism behind its purification using affinity chromatography, separating it from inactive contaminants. Pharmacia

Fine Chemicals are leaders in affinity chromatography and our long experience in this technique is exploited in the production of our receptor-specific proteins. You get proteins which are pure, biospecific and fully active. Freeze-dried and salt-free. Ready for use on reconstitution with buffer.

Can we be more specific? Contact your usual supplier of Pharmacia products for further information on receptor-specific proteins.

A basic question concerning applied research:

Will your next research project establish the basis for developing an innovative product with significant commercial appeal?

If your answer is an unqualified yes, you may be eligible for a

TECHNICON RESEARCH GRANT

The Technicon Science Center in Tarrytown, New York, where Technicon Instruments Corporation, international leader in automated clinical analysis, conducts extensive research and development programs.

THIS CAN MEAN:

- Research support of up to \$100,000 per year.
- Royalty payments on patents if Technicon is able to develop a marketable product following completion of the research.

CATEGORIES

Following are examples of acceptable topics:

- Automated measurement of physiologic constituents, or medical diagnostic instruments generally.
- Non-invasive diagnosis of internal organs or measurement of physiologic functions.
- Detection of dental pathology.
- Veterinary diagnostic instruments.
- Instruments for industrial, agricultural or environmental measurement.

WHO IS ELIGIBLE

Grants are available to scientists at colleges, universities, medical centers and non-profit research institutes in North American, Western European and Mediterranean countries.

HOW TO PROCEED

Do not send a proposal at this time. Write to one of the following addresses for further information and a "Preliminary Submission Form." Deadline for full proposals is December 15, 1978.

In North America, write:
Technicon Research Grants Program
c/o Morris H. Shamos, Ph.D.
Technicon Instruments Corporation
Tarrytown, New York 10591

In Western Europe and the Mediterranean area, write:
Technicon Research Grants Program
c/o Harry W. Holy, Ph.D.

Tomorrow's Technology Today™

Lysosomal and mitochondrial heat labile enzymes in ageing human fibroblasts

ONE of the characteristic changes associated with the ageing of human fibroblasts in cell culture is the presence of increasing amounts of altered molecules¹⁻³. Such alterations have been detected for at least three cytoplasmic enzymes: glucose-6-phosphate dehydrogenase (G6PD), 6-phosphogluconate dehydrogenase and hypoxanthine-guanine-phosphoribosyl-transferase. For each enzyme, the proportion of molecules which are modified reaches as much as 25% in cells of the last generations. The origin of these alterations is still only an hypothesis. Some authors¹, in agreement with Orgel's error catastrophe theory⁴, suggest that they are the result of a faulty synthesising machinery; others⁵⁻⁷, however, suggest that they are due to a post-translational effect. We present here a study on the heat lability of some lysosomal and mitochondrial enzymes to test whether the alterations also affect proteins present in these subcellular entities. We compare the results with the predictions of the above hypotheses, and suggest that they probably are best explained in terms of a post-translational modification.

Experiments were carried out on normal human fibroblasts (WI-38). Using Hayflick's method⁸, these cells were cultured and the population was split 1:4 every week. Cells from confluent cultures were collected, homogenised and heated to high temperatures so as to control the denaturation rates of the enzymes (Fig. 1 and Table 1). Five enzymes were tested: *N*-

acetyl- β -D-glucosaminidase (NA β Glu), α -D-glucosidase (α Glu) and *N*-acetyl- α -D-galactosaminidase (NA α Gal), all located in the lysosomes, and sulphite cytochrome *c* reductase and G6PD, located in the mitochondria and cytoplasm, respectively. For NA β Glu, only isoenzyme B was considered. Isoenzyme A, which had first been inactivated by incubating the homogenate for 60 min at 37 °C in an imidazole-HCl buffer at pH 7 (ref. 11), was responsible for 10% of the enzyme activity in both young and old cells. The protein concentration of the homogenate was adjusted to obtain accurate assays on the enzymes (Table 1). The slight variations in the protein content of the homogenate did not affect the denaturation rates of the enzymes but we added albumin to serve as a protective agent when high dilutions of this homogenate were required. On the other hand, temperature and pH controls were crucial in such experiments. Two cell populations from the same line were compared: those from passages 22-25 and those from passages 42-45, which had completed 46-53% and 89-96% of their maximum lifespan, respectively. The maximum lifespan was observed on cells of the same lineage.

The experimental points presented in Fig. 1 were subjected to a factorial two-way analysis of the variance and showed a non-significant time-age interaction except for a significant interaction with G6PD ($P < 0.01$). When this enzyme was tested in the old cells, the deviation of the curve from linearity was significant ($P < 0.05$) and the experimental values fitted best by superposing two decreasing exponentials; the first one, with the steeper slope, represented the denaturation rate of the heat-labile G6PD, and the second one, that of the unaltered enzyme. The latter was responsible for 77% of the enzyme activity. Thus, in the analysis made in our laboratory, only the G6PD was altered in the old cells. The experiments were

Fig. 1 Inactivation curves of enzymes from young and old WI-38 fibroblasts. Confluent cultures were rinsed with phosphate buffered saline (PBS) and the cells were collected with a rubber policeman. They were then washed twice with 0.25 M sucrose solution and homogenised by 20 strokes of the tight pestle of a Dounce homogeniser (Kontes). For the assay of sulphite cytochrome *c* reductase, the cells were disrupted with an ultraturax. The homogenates were heated in the incubation medium to the temperatures critical for the denaturation of the enzymes. At given times, samples were removed and tested for their residual enzyme activity. The experimental conditions are summarised in Table 1. Enzyme assays were introduced following methods already published but with slight modifications, that is, NA β Glu, α Glu and NA α Gal were tested with umbelliferyl derivatives⁹ at pH 3.5, 4.5 and 4, respectively; sulphite cytochrome *c* reductase as originally described at pH 8.5 (ref. 10); the preparation of the extract and the assay of the G6PD were carried out following the method of Holliday and Tarrant¹. Results were expressed

Table 1 Experimental conditions for the inactivation curves

Enzyme tested	Range of the protein concentration of the homogenate (mg ml ⁻¹)	Buffer	pH	Other components	Temperature of incubation (°C)
N-acetyl- α -D-galactosaminidase	1-1.5	5 mM acetate	4	Albumin 1 mg ml ⁻¹	62
N-acetyl- β -D-glucosaminidase	0.003-0.005	50 mM citrate	3.5	Albumin 1 mg ml ⁻¹	49
α -D-glucosidase	0.1-0.15	10 mM acetate	4.5	Albumin 1 mg ml ⁻¹	63
Sulphite cytochrome c reductase	5-8	3 mM imidazole-HCl	8.5	Sucrose 0.25 M	58
Glucose-6-phosphate dehydrogenase	1.5-2	50 mM Tris-HCl	8	Mercaptoethanol 1 mM EDTA 1 mM α -amino-n-caproic acid 1 mM NADP 1 mM	60

repeated at least twice, as described above, and once again at a lower temperature (2 °C below that indicated); within a range of 2-5% no alteration could be detected for the lysosomal and mitochondrial enzymes.

Holliday and Tarrant¹ showed that some cytoplasmic enzymes are modified during the ageing of human MRC 5 fibroblasts in culture. We confirmed these results with WI-38 cells and found that the percentage of heat-labile G6PD observed in old populations is similar in both cell strains. To explain the appearance of altered enzymes in old cells, Orgel's error catastrophe theory of ageing¹² was proposed¹. This theory suggests that all the enzyme molecules would be modified, as they are synthesised by faulty machinery. However, we show that at least four enzymes are not significantly modified during the ageing process. One explanation for the fact that modifications would not be detectable in these molecules is that the altered enzymes would be completely inactive. This eventuality is rather improbable, for a misincorporation of amino acids produces considerable heterogeneity in the loss of enzyme activity¹³. The hypothesis of a post-translational modification explains more easily how alterations occur in only some enzymes. Several results have been published supporting this explanation¹⁴⁻¹⁸, but discussion on the subject remains open¹⁹⁻²¹. The presence of unaltered enzymes in lysosomes and mitochondria, apart from the modified cytoplasmic enzymes, also suggests that the alteration could be specific to certain cellular compartments. However, the analysis of many more enzymes would be necessary before we could generalise this hypothesis. Note also that not all the cytoplasmic enzymes are modified, for phosphoglucose isomerase was found to be unaltered in old cell cultures²². In conclusion, the fact that four enzymes located in lysosomes and mitochondria are not modified during the ageing of cell cultures suggests that the error catastrophe theory is not a satisfactory explanation for the presence of such alterations in some cytoplasmic enzymes.

We thank Mrs A. Genette, E. Feytmans and E. Depiereux for the statistical analysis of the results and Mrs A. Houbion for assistance. The work was supported by the "Belgian Fondation Universitaire pour l'étude des processus du vieillissement". The WI-38 cells were obtained from the American type culture collection.

Initiation of chemical carcinogenesis requires cell proliferation

CELL proliferation has often been implicated in the development of cancer with chemicals¹⁻³. Supportive evidence for this is the observation that several carcinogens that normally do not induce liver cancer in intact adult animals, especially with a single dose, become carcinogenic if administered as a single injection after partial hepatectomy (PH)¹. In these conditions, it is thought that PH may act during initiation, presumably by fixation of some carcinogen-induced DNA damage through replication of the altered DNA. However, because carcinogenesis is a multi-step process, often involving the appearance of several new cell populations between the initial target cells and the ultimate cancer^{4,5}, it is possible that the regenerative response of liver following PH could have a major effect on one or more steps subsequent to initiation. Thus, the use of a very late end-point (cancer) makes it difficult, if not impossible, to relate with any accuracy some very early event to any specific step in the carcinogenic process. Solt and Farber⁶ have recently developed a new approach to the sequential analysis of carcinogenesis *in vivo* that delineates the first few steps in the process and is a quantitative assay for initiation of liver cancer. We have used this model to investigate whether cell replication exerts its first effect on initiation or on some later step in the carcinogenic process. And if initiation is at least one site of action, when in the regenerative cell cycle is a carcinogen most effective and what biochemical events might be involved at this phase of the cell cycle?

The assay⁶ is based on the hypothesis that an early, if not the first, cell is resistant to the inhibitory effect of carcinogens on cell proliferation. It consists of the measurement of the number of foci of carcinogen-altered hepatocytes that are capable of responding to a stimulus for cell proliferation in the presence of a strong inhibitor of normal cell proliferation (for example, low dietary level of 2-acetylaminofluorene, 2-AAF). The combined dietary 2-AAF plus PH creates a strong selection pressure for

the growth of carcinogen-induced putative initiated cells, but does not by itself induce such changes in the experimental conditions used^{6,7}. The foci of altered cells can readily be identified either grossly or with the histochemical use of γ -glutamyl transpeptidase (γ -GT) activity, an enzyme that is a marker for pre-neoplastic liver lesions in these conditions⁷⁻¹⁰. In addition, with a single dose of at least one chemical carcinogen, diethylnitrosamine (DEN), as the initiating carcinogen and with this model, hepatocellular carcinoma develops in the majority of rats within 8 months⁷. The cancers are seen to arise within hyperplastic nodules which in turn are derived from foci of altered resistant hepatocytes⁷. For example, with a large initiating dose of DEN, such as 200 mg per kg, approximately 10^3 foci appear in a 5-g liver during selection, of which about 10^2 develop into persistent hyperplastic nodules. One to five hepatocellular carcinomas develop from such nodules.

For this study, a potent carcinogen for many tissues or organs and one not requiring metabolic activation, *N*-methyl-*N*-nitrosourea (MNU), was selected. This compound is not a carcinogen for intact liver despite its extensive methylation of DNA and other liver macromolecules¹¹, but becomes one when administered after partial hepatectomy¹². MNU was administered intraperitoneally (i.p.) to male Fischer rats (F-344). Three hours later, a time at which no further MNU could be detected in the blood or in the liver (E.C. and D.S.R.S., unpublished), the animals were subjected to either 67% partial hepatectomy or sham operation (SO). After a recovery period of 2 weeks, all the rats were exposed to the selection procedure favouring the growth of the putative initiated hepatocytes over the surrounding hepatocytes. This consisted of dietary 2-AAF plus the liver mitogen, α -hexachlorocyclohexane (α -HCH)¹³, as shown in Fig. 1.

The results presented in Table 1 show that foci of resistant phenotypically altered hepatocytes, positive for γ -GT, were seen in rats which received MNU and which were partially hepatectomised. Very few foci were seen in the animals receiving MNU+SO, vehicle+PH or no MNU. A similar pattern of results was obtained using male Wistar rats. Also, when CCl_4 replaced the α -HCH as a stimulus for cell proliferation, significant numbers of γ -GT-positive foci were again seen only in rats receiving MNU plus PH. Recent results in experiments designed to determine the time relationships between the administration of MNU and PH for optimal initiation indicate that MNU is a much more efficient inducer of putative initiated cells when administered 18 h after operation (129 foci cm^{-2}). The degree of initiation falls off rapidly with administration of MNU before 16 h or after 24 h following partial hepatectomy.

Table 1 Effect of partial hepatectomy on the induction of γ -GT-positive foci in the liver by MNU

Treatment	α -HCH		CCl_4
	Fischer	Wistar	Fischer
MNU+PH	$7.4 \pm 2.5(4)$	12.6 12.5	20.3 26.0
MNU+SO	$0.6 \pm 0.2(4)$	0.9 0.3	$0.8 \pm 0.5(4)$
Citrate+PH	$0.2 \pm 0.1(4)$	0.3 0.5	$0.5 \pm 0.3(4)$
MNU, no operation	0.7 0.4	—	—
No MNU, no operation	—	$0.6 \pm 0.2(5)$	—

For scoring purposes, we used the characteristic histochemical staining for γ -GT, as described by Rutenburg *et al.*¹⁸, with which the selected foci stain dark red and the surrounding normal hepatocytes show no staining. γ -GT-positive foci were counted by low power microscopy and the numbers expressed as foci cm^{-2} of section area (mean $\pm$ s.e.m.). The number of animals is in parentheses. All the groups were selected by exposure to 0.02% 2-AAF plus CCl_4 or α -HCH, as detailed in the legend to Fig. 1.

Fig. 1 Adult male Fischer 344 rats (Canadian Breeding Farms and Laboratories) were given a single dose of *N*-methyl-*N*-nitrosourea (60 mg per kg, i.p. in 10 mM citrate buffer pH 6.0). After 3 h they were either submitted to partial hepatectomy (PH) or sham operated (SO). Control groups received MNU and no operation, citrate buffer and PH, or citrate buffer and SO. Two weeks later, all the animals were placed on a diet containing 0.02% 2-AAF in order to create a 'mito-inhibitory' effect, and 1 week after starting the 2-AAF diet they were subjected to a stimulus for liver cell proliferation by force-feeding α -HCH, at a dose of 150 mg per kg dissolved in corn oil, on days 7 and 9 after commencing the 2-AAF diet, or a single dose of CCl_4 (0.25 ml per 100 g in corn oil). After a total period of 14 days on 2-AAF diet, the rats were placed on the stock diet devoid of AAF for 7 days. At the end of this period, they were killed and liver samples were processed for histological and histochemical studies. To monitor the effectiveness of the selection procedure, rats previously initiated with diethylnitrosamine (DEN: 100 mg per kg, i.p.) were also included at the start of the 2-AAF diet. Open bar, 1 week basal diet; hatched bar, 1 week basal diet + 0.02% AAF.

These data clearly indicate that initiation of carcinogenesis with MNU is intimately related to some change in the liver that occurs after removal of two-thirds of the liver.

We have not yet established that the administration of MNU in partially hepatectomised rats in the conditions used in these experiments leads to liver cancer. However, there is considerable circumstantial evidence in support of this. For example, (1) MNU in similar conditions has been found to be carcinogenic for the rat liver in two laboratories^{12,14}; (2) the foci induced by MNU, like those induced by DEN and other liver carcinogens, are positive for γ -GT, a marker enzyme for pre-neoplastic and neoplastic hepatocytes⁸; and (3) the foci are indistinguishable in their appearance and early behaviour from those induced by DEN and the latter have been shown to be precursors for liver cancer⁷.

Although the mechanism by which cell proliferation stimulates the induction of putative pre-neoplastic hepatocytes is not known, replication of carcinogen-damaged DNA before repair offers an attractive mechanism by which the carcinogen-induced DNA damage may be fixed and may thus increase the chances of altered nucleotide sequences in the newly made DNA. In support of this hypothesis, it has been demonstrated that liver DNA containing carcinogen-induced lesions such as those induced by MNU (D.S.R.S., S. Rajalakshmi and P. M. Rao, unpublished observations), dimethylnitrosamine^{15,16} and *N*-hydroxy-2-acetylaminofluorene¹⁷ replicates *in vivo*. Such a phenomenon is not lethal for the cell, since the newly made DNA on the damaged templates is stable *in vivo* for at least one month. Interestingly, several liver carcinogens are necrogenic and induce compensatory liver cell proliferation; some of these induce resistant foci without the need for an exogenous mitogen such as PH (refs 6, 7).

The observation that cell replication seems to be necessary for the induction of putative initiated hepatocytes by MNU suggests that initiation of carcinogenesis may consist of at least two steps: (1) interaction of a carcinogen or its activated derivatives with target molecules, possibly DNA, to induce an appropriate biochemical lesion, and (2) the 'fixation' of the lesion or lesions by a round of cell replication. Such a concept would imply that one or more cellular events closely related to cell replication are an integral part of the initiation process with chemical carcinogens. The similarity between initiation of cancer development with chemicals and transformation of cell cultures with DNA viruses and X rays¹⁹⁻²¹ is noteworthy in that they both require at least one round of cell proliferation. The possibility that the initiating carcinogen is selecting a preformed altered cell rather than inducing a new one *de novo* is thought to be unlikely because of the following observations. (1) No foci of altered cells are selected without previous exposure to the carcinogen. (2) The foci observed are distributed randomly throughout the hepatic parenchyma, despite the striking zonal organisation of the liver. In addition, the demonstration that a carcinogen can permanently alter the progeny of a single cell in culture²² supports the hypothesis that the foci we observe represent a *de novo* induction phenomenon.

The possible role of altered DNA or other macromolecules and of the repair of such damage is now being analysed with this model.

C-type viral antigen expression in human placenta

THE evidence of C-type virus expression in man includes electron microscopic observation of virus-like particles in 30-50% of a small number of human placentas¹⁻⁴. Because of the limitations of ultrastructural surveys (sample number, specimen size, false negatives) we attempted to detect C-type virus expression in human placenta by indirect immunofluorescence using antisera raised against HEL-12 virus; this is a C-type retrovirus recovered from human embryonic lung cells after *in vitro* cultivation⁵. We demonstrate here C-type virus-related antigen

in 24 of 24 term placentas. The specificity of the immunofluorescence reaction for viral antigen was confirmed by serum absorption tests with purified virus. Preliminary isolation of the reactive antigen from placenta yielded a glycoprotein-rich fraction (β - μ) which blocked binding of anti-HEL-12 virus antiserum with placenta. In addition, antisera raised against β - μ reacted with HEL-12 virus-infected cells as well as with human placenta.

A survey of 24 normal full-term placentas was carried out with anti-HEL-12 virus antiserum. The HEL-12 virus antiserum was prepared by hyperimmunisation of rabbits with gradient-purified HEL-12 virus. The antiserum reacts with HEL-12 virus infected cells of several species but not with uninfected controls⁶. In addition, anti-HEL-12 virus antiserum has not been found to react with normal adult tissues^{6,7}. Comparable samples from the maternal surface of each placenta were quick-frozen in isopentane, usually within 1 h and no longer than 5 h after delivery, and then sectioned. Using a previously described technique⁶, all placentas exhibited the same distinctive pattern of fluorescence with anti-HEL-12 virus antiserum (Fig. 1a). For comparison, a light micrograph of a serial section of the same placenta is presented in Fig. 1b. Arrows indicate the areas in which immunofluorescence was detected. Fluorescence was predominantly associated with cells

Fig. 1 Immunofluorescent reaction in human placenta P28V. *a*, 4 μ m cryostat sections of human placenta (P28V) were washed in PBS and fixed in ether-ethanol (1:1) for 5 min followed by 95% ethanol for 20 min at 25 °C. Sections were then incubated with anti-HEL-12 virus antiserum (1:20) for 30 min in a moist environment at 25 °C, washed three times with PBS, stained with goat-anti-rabbit IgG-FITC conjugate (Behring) for an additional 30 min, and then washed again three times with PBS. Slides were examined with UV illumination using an Olympus BHA fluorescence microscope fitted with an FITC filter and a vertical ultraviolet illuminator. The reaction shown is typical of all of the placentas examined. *b*, A serial section of P28V was fixed in formalin and then stained with haematoxylin and eosin. The syncytiotrophoblast (s), cells of the villous stroma (v) and position of maternal (m) and fetal (f) circulation are marked. The arrows indicate the areas in which immunofluorescence was detected.

Table 1 Indirect immunofluorescence of human placenta with C-type viral antisera

Antisera (serum dilution)	Absorbent	Concentration (μ g protein)	Immunofluorescence	No. of placentas examined
Premune rabbit (1:20)	—	—	—	24
Rabbit anti-HEL-12 (1:20)	—	—	+	24
Rabbit anti-HEL-12 (1:20)	HEL-12 virus	25	—	5
Rabbit anti-HEL-12 (1:20)	SiSV	25	+	2
Rabbit anti-HEL-12 (1:20)	—	150	trace	2
Rabbit anti-HEL-12 (1:20)	BaEV	25	+	2
Rabbit anti-HEL-12 (1:20)	—	150	trace	2
Rabbit anti-HEL-12 (1:20)	β - μ (3 preparations)	40	—	4
Rabbit anti-HEL-12 (1:20)	RSV	150	+	4
Rabbit anti-HEL-12 (1:20)	Fetal calf serum	1,800	+	2
Rabbit anti-HEL-12 (1:20)	Bovine serum albumin	200	+	2
Rabbit anti-HEL-12 (1:20)	Human serum albumin	200	+	2
Rabbit anti-HEL-12 (1:20)	Haemoglobin	200	+	2
Rabbit anti-HEL-12 (1:20)	Human IgG	200	+	1
Goat-anti-SiSV (1:5)	—	—	+	2
Control goat (1:2)	—	—	—	2
Rabbit-anti-BaEV (1:2)	—	—	—	2

Indirect immunofluorescence of human placenta with C-type viral antisera. Antisera were used in indirect immunofluorescence tests⁶ with frozen sections of human placenta as described in the legend to Fig. 1, with or without previous absorption. Absorption was carried out incubating 50- μ l volumes of anti-HEL-12 virus antiserum (1:20) with 25–1,800 μ g of absorbent protein for 1 h at 25 °C and 18 h at 4 °C. Protein concentration was determined by the method of Lowry²². HEL-12 virus was purified as described⁵. Fetal calf serum (Gibco), human and bovine serum albumins (Pentex), haemoglobin (Sigma) and human IgG (Pentex) were diluted immediately before use. Secondary antisera were goat-anti-rabbit IgG-fluorescein isothiocyanate (FITC) and rabbit-anti-goat IgG-FITC antisera (Behring). Slides were evaluated under code by two independent observers. Each placenta specimen gave the reaction indicated. Specimens were negative (–), positive (+) or trace, a fluorescent reaction which was greatly reduced as compared with positive sample but which could be distinguished from negative samples.

of the villous stroma surrounding vessels carrying fetal blood. No significant fluorescence was found in syncytial trophoblast cells, which are in contact with maternal blood. The fluorescence pattern is consistent with what might be expected if the zone of antigenicity was delineated by the basement membrane between the syncytial trophoblast and the villous stroma. Neither the preimmune serum nor the fluorescein conjugate alone reacted with any placenta. Replicate sections of 10 placentas stained with twofold serial dilutions of antiviral antiserum showed a common endpoint of 1:40, suggesting that they contained a comparable amount of antigen.

Specificity of immunofluorescence was tested by serum absorption. Anti-HEL-12 virus antiserum was absorbed with gradient-purified simian sarcoma virus (SiSV), baboon endogenous virus (BaEV), Rous sarcoma virus (RSV) and HEL-12 virus. Table 1 shows that only HEL-12 virus blocked the reaction completely at the concentrations of virus used. SiSV and BaEV mediated partial absorption, as might be expected, for HEL-12 virus crossreacts with both although they do not crossreact with each other^{5,8,9}. RSV did not block the reaction. Bovine and human serum albumins, immunoglobulin and haemoglobin, at concentrations 10-fold in excess of that needed for HEL-12 virus to absorb, and a 70-fold excess of fetal calf serum, did not block the reaction. Antisera to SiSV and BaEV were tested for reactivity with placenta (Table 1). Both sera detect multiple components of HEL-12 virus as determined by immunoprecipitation and acrylamide gel analysis (J. T. Reynolds, unpublished observations). Anti-SiSV predominantly reacts with the viral envelope whereas anti-BaEV detects a wide range of virion components. Concentrated anti-BaEV antiserum did not react with placenta whereas anti-SiSV antiserum mediated a similar fluorescence pattern to that seen with HEL-12 virus antiserum. The data indicate that anti-HEL-12 virus antiserum reacts specifically with normal human placenta by detecting antigen which crossreacts with a primate C-type virion component. The inability of anti-BaEV antiserum to react with placenta compared with the effectiveness of concentrated BaEV in serum absorption tests with anti-HEL-12 virus antiserum most probably reflects a low antibody titre of the anti-BaEV antiserum for antigenic determinants shared by HEL-12 virus, BaEV and human placenta.

As C-type viral antigens are found at infected cell surfaces¹⁰, a procedure designed to elute cell surface components was used in an attempt to isolate the reactive placenta antigen¹¹. Reactive antigen was monitored during the isolation procedure by the ability of fractions to inhibit immunofluorescence in serum absorption tests. The chorionic membranes and umbilical cords were removed from placenta and the remaining tissue was homogenised and incubated with 3 M KCl for 18 h at 4 °C. The eluted material which was soluble in deionised water was chromatographed on G-100 Sephadex in phosphate-buffered saline (PBS), pH 7.3 (Fig. 2). Protein eluting between 70–80,000 MW, fraction 2, was the most active in serum absorption tests. This fraction was separated by chromatography with concanavalin A-coupled Sepharose (Con A) and a Con A binding fraction (β - μ) was eluted with α -methylmannoside. 40 μ g of this glycoprotein-rich fraction completely blocked the reaction of anti-HEL-12 virus antiserum with placenta (Table 1). In contrast, as 100 μ g of Sephadex fraction 2 was required for comparable inhibition, Con A chromatography selects for material which is increased in specific activity for the reactive

Table 2 Indirect immunofluorescence with anti- β - μ antiserum

Target cell	Infecting virus	Species	Immunofluorescence with antiserum against HEL-12 virus		
			β - μ	HEL-12 virus	Premune sera
HEL-12 p 21	HEL-12	human	+	+	—

Rabbit antisera were diluted 1:80 and used in indirect immunofluorescence tests with virus-infected or control cells grown *in vitro*²³. The secondary anti-serum, goat-anti-rabbit IgG-FITC (1:20) did not react with any cell by itself. Positive immunofluorescence with tissue culture cells was granular and apple green and confined to the cytoplasm. Slides were evaluated under code.

Fig. 2 Fractionation of KCl extract of human placenta. 200–300 g of placenta were obtained by removing the chorionic membrane from freshly delivered human placentas and washing the resultant material with PBS. Three 5-s homogenisations in a Waring blender were followed by treatment for 10 min with 0.85% NH_4Cl at 4 °C and the pellet obtained was treated with PBS containing 3 M KCl for 18 h at 4 °C. The resultant supernatant was extensively dialysed against 0.85% NaCl followed by deionised water. The water-soluble fraction was then concentrated by pressure dialysis and 20–50 mg in 1–1.5 ml was applied to a 150-ml Sephadex G-100 (Pharmacia) column (a). The column was run at a flow rate of 10 ml h^{-1} with PBS, 0.2% NaN_3 , pH 7.0, as the buffer. 2.0-ml fractions were collected and monitored at a wavelength of 280 nm in a Gilford 240 spectrophotometer. The column was calibrated with blue dextran, bovine serum albumin (BSA), and ribonuclease. Fractions were tested in serum absorption tests as described in Table 1. Based on such tests, the fraction shown shaded was selected and applied to a 10-ml column containing Con A-Sepharose (Pharmacia) (b). The column was then rinsed with four column volumes of normal saline, 0.05 M phosphate and 0.2% NaN_3 , pH 7.0, at a rate of 6.0 ml h^{-1} . This was followed by a 10% solution of α -methylmannoside (Sigma). 1.0-ml fractions were collected. The α -methylmannoside eluate was concentrated by pressure dialysis and used for serum absorption tests and immunisation.

placental antigen. β - μ preparations were isolated from three placentas and each preparation blocked the reaction of anti-HEL-12 virus antiserum with specimens from several different placentas.

To substantiate that β - μ contained antigen related to HEL-12 virus, an antiserum was raised in a rabbit against β - μ . Table 2 shows that this anti- β - μ antiserum reacted with virus-infected cells and human placenta but not with uninfected control cells. Preimmune serum did not react with any specimen.

Although we previously reported HEL-12 virus-related antigen and antibody in some tissue from patients with systemic lupus erythematosus⁶⁻⁹, this is the first report of virus-related antigen in all specimens tested of a selected normal human tissue. The placenta may be a privileged site of C-type viral expression in man, as has been suggested for sub-human primates^{2,12}. Factors allowing placenta to be such a privileged site may include hormonal modulation of viral replication^{13,14} and the suspension of some immune mechanisms¹⁵.

The reaction of antiviral antiserum was predominantly associated with cells in contact with fetal blood whereas the rare particles reported in electron microscopic studies¹⁻⁴ were found at the surface of cells bathed by maternal blood. This difference in the location of antigen and maturing particles is of interest in

view of the observation that mammalian cells often contain proviral DNA of non-crossreactive C-type viruses¹⁶. Four unrelated classes of C-type viruses have been described in primates¹⁷⁻¹⁹. In placenta, the virions detected morphologically and the antigen detected by fluorescence may be related. The apparent absence of fluorescence in the syncytiotrophoblast may indicate that viral expression is restricted to small focal zones whereas viral expression in the cells of the villous stroma is widespread. Furthermore, virions in the villous stroma may not yet have been detected. Alternatively, the virions and β - μ antigen may not be antigenically related. In addition, there is evidence that C-type viral antigen may be transiently expressed during gestation^{20,21}.

We have consistently detected the presence of a component of human placenta which crossreacts antigenically with the C-type retrovirus HEL-12. We are able to isolate a fraction from placenta which inhibits this reaction of anti-HEL-12 virus antiserum with placenta and an antiserum prepared to this antigen reacts with placenta as well as with HEL-12 virus-infected cells. We have not determined the site of β - μ synthesis, nor do we know the chronology of its expression during gestation. Experiments are in progress to explore these questions as well as to characterise the complexity of β - μ and determine its presence in fetal tissue.

This work was supported by the Elsa U. Pardee Foundation, a Basil O'Connor Starter research grant from the NF, March of Dimes and CA 19264 from the NCI. We acknowledge the assistance of Drs P. Graff, N. G. Ordóñez, W. H. Kirsten and E. Kleff and Ms H. Dalton. RSV and anti-SiSV antiserum were obtained through the Office of Program Resources and Logistics, NIH.

Induction of extensive fimbrial branching in the adult rat brain

It is now well known that some central nervous system axons can regenerate following axotomy^{1,2} or sprout in reaction to nearby denervation³. The cholinergic projection from the septal nuclei to the hippocampal formation has demonstrated the ability both to regenerate^{4,5} and sprout^{6,7}. However, the possibility that axons in the mature mammalian brain can be induced to grow in other circumstances has not been investigated. We have examined the ability of the axons of the

fimbria, the fibre bundle which interconnects the septal nuclei and the hippocampal formations, to grow in circumstances other than those used in classical regeneration and sprouting research. The fimbria is particularly suitable for the study of axonal growth in brain as its fibres run as an unbranched bundle, with one surface exposed to the lateral ventricle and thus free from surrounding neuropil. Consequently, it is readily accessible for experimental manipulation. We demonstrate here that fibres of the fimbria in the adult rat brain can be induced to grow in circumstances that neither sever them nor denervate regions to which they normally project.

We used adult albino rats (380–470 g, Sprague-Dawley from Simonsen Labs). All rats, under Nembutal anaesthesia, had their right fimbria exposed at the juncture of the septum, fimbria and anterior hippocampus. A flap of skull was removed for 2 mm on either side of the landmark bregma, and extending from the mid-sagittal suture to the edge of the dorsal surface of the skull. The dura was removed and the cortex, corpus callosum and caudate nucleus overlying and adjacent to the fimbria were aspirated. In some experiments the fimbrial fibres were left untreated, and in other experiments the fimbria was cut with a scalpel or treated for 10 min with a cotton swab containing either 1 μ g of NaCl or 1 μ g of colchicine. The wound was then rinsed with sterile saline and filled with Gelfoam. About two months after surgery animals were anaesthetised and perfused transcardially with a 10% formaldehyde-saline solution (a few animals were perfused with glutaraldehyde for ultrastructural observations). The brains were removed and post-fixed in the perfusion solution before staining and histological analysis. Additional animals were killed at 4 and 11 d after treatment to determine short-term effects of the experimental treatment.

We have previously found that after the fimbria has been cut or crushed the fibres do not regenerate. However, a less traumatic lesion, by freezing the fimbria, produced a most unusual outcome. In some animals, following freeze lesions of the fimbria, a bridge containing nerve fibres and glial and epithelial cells was seen to originate from the fimbria, cross the ventricular space and make contact with the lesioned caudate nucleus⁵ (Fig. 1a, b). These seemed to be regenerating fibres that for some reason could not pass through their normal trajectory and instead followed a path towards the caudate nucleus. However, during experiments on the trophic regulation of synaptogenesis in the mature rat brain we observed that the cotton swab application of colchicine to the fimbria often induced an outgrowth of fimbrial fibres. In some cases these fibres bridged the ventricular space between the fimbria and caudate nucleus. Initially, we suspected that these fibres had regenerated following colchicine-induced damage of the fimbria; however, this interpretation was unlikely in view of morphological evidence that the cotton swab-colchicine application caused very little, if any, fibre destruction (D.G. and C.W.C., in preparation). Accordingly, we proceeded to determine if the application of a cotton swab with salt crystals, or the mere surgical procedure of exposing the fimbria, could induce fimbrial fibres to grow towards the lesioned caudate nucleus.

An outcropping of fibres from the fimbria was seen 30–60 d after cotton swab-NaCl treatment of the fimbria in 13 of 15 cases, and in 5 of these cases there was also an outgrowth of fibres from the lateral septum. These fibres arched out from the fimbria (or septum) but usually curved back and followed a normal trajectory. In material stained for acetylcholinesterase (AChE) a single fibre could be observed to depart from its normal linear trajectory and curve towards the caudate among a tangle of other axons and glial cells. Many axolemmal bulges or varicosities were present in these axons (Fig. 3a). Such varicosities were rarely seen in the normal fimbria. In five of these 15 cases fibres were observed to travel in a dense glial matrix across the lateral ventricle where they contacted the partially damaged caudate (Fig. 2a, b). The marked enrichment of glial cells in the branch was not seen in the normal fimbria.

Fig. 1 a, Photomicrograph of fibre-stained, horizontal section of rat brain 60 d after freezing of fimbrial fibres. Paraffin sections were stained with the Holmes' silver method¹² to demonstrate nerve fibres. The branch is seen to extend from the fimbria (f) to the caudate nucleus (c). Contralaterally, the fimbria and caudate nucleus are intact. Scale bar, 500 μ m. b, Enlarged portion of fimbrial branch to caudate nucleus showing nerve fibres travelling in a mesh of glial cells. Scale bar, 50 μ m.

The fibres in the branch clearly adjoined the caudate neuropil, but it was less clear whether they actually entered it. Ependymal cells lined the rostral surface of the branch and were apparently continuous with the ependymal lining of the fimbria and caudate.

In the initial stages of this apparent growth process, a damming up of AChE-positive material was seen at 4 d post-treatment. By 11 d post-treatment axons could be observed which deviated from their normal pathway and displayed swollen regions along their course (Fig. 3b). These changes were specific to the areas of cotton swab application.

The growth of fimbrial fibres towards the caudate did not seem to be related to the destruction of the fibres, as (1) at short times after treatment, staining for AChE remained normal in the hippocampus (see Fig. 2a) (in contrast to the marked depletion of AChE staining seen after fimbrial lesions⁸); (2) there was little apparent lethal fibre damage in the fimbria as determined by light and electron microscopy; (3) at 4 d after treatment, many normal axons were observed to travel laterally towards the caudate instead of taking the usual longitudinal course along the hippocampal formation; (4) in four cases of complete section of the fimbria no fibre outcroppings were observed.

The conditions for the initiation of growth seemed to depend on two factors. First, some type of mechanical disturbance seemed necessary to elicit growth. In 9 animals whose fimbriae were exposed but left untreated there was only one case where fimbrial fibres grew out towards the caudate. This is in contrast to the cotton swab-NaCl treatment of the fimbria where in 5 of 15 cases fimbrial fibres reached the caudate nucleus. However, in the extreme instance of freezing the fimbrial fibres, axonal growth occurred frequently but involved very few fibres. The most prolific growth occurred with cotton swab applications. It may be that the mechanisms of growth induction are common to all these cases but that in the mere exposure of the fimbria the disturbance is too small, whereas in the freezing of fimbrial

Fig. 2 *a*, Photomicrograph of AChE-stained, horizontal sections from rat brain 32 d after cotton swab-NaCl treatment of the fimbria. Section stained for AChE after the method of Matthews *et al.*¹³. The left side shows the normal course of fimbrial fibres travelling uninterrupted from the septum (*s*) to the ventral hippocampal formation (*vh*). The intact caudate nucleus is lateral to the fimbria. The right side shows the fimbria branching off towards the lesioned caudate nucleus. Although there is a disruption of fibres in the fimbria there is no depletion of AChE-staining in the ventral hippocampal formation. AChE-staining of the ventral hippocampal formation is almost completely eliminated by section of the fimbria⁸. In silver-stained material the branch is observed to contain many axons, of which only a small percentage stain positively for AChE. Calibration bar = 1 mm. *b*, Enlarged portion of boxed-in area of Fig. 2*a*, demonstrating AChE-positively staining fibres. Some of these fibres are shown to pass from the fimbria to contact the lesioned caudate in two separate regions, whereas other fibres continue posteriorly to the ventral hippocampal formation. Scale bar, 200 μ m.

fibres the extreme damage is a hindrance to growth. Second, the proximity of a lesioned caudate nucleus was apparently a condition for successful fibre outgrowth. In animals where most of the head of the caudate had been removed (the regions closest to the perturbed fibres of the fimbria) little, if any, growth of fimbrial fibres was observed. Other regions of close proximity to the fimbria, such as the thalamus, hypothalamus

and corpus callosum, were never targets for the outgrowing fibres.

We cannot specifically identify the nature of the perturbation that will initiate fibre growth. However, we feel that the cotton fibres from the swab, the mechanical disturbances of exposing the fimbria or the freezing of fimbrial fibres all act to irritate the fimbria and that this irritation induces nerve growth. The partially denervated cholinergic cells of the caudate nucleus may produce substances which attract and stimulate the growth of cholinergic fibres of the fimbria that have been prompted to grow. The role of factors such as fibre perturbations and the attractive influence of denervated tissues in stimulating and sustaining axonal growth is very similar to those factors hypothesised by Cajal, Nageotte and Marinesco to be critical for growth of axons in the periphery and spinal cord of the mammalian nervous system⁹. Seiger and Olson have shown that locus coeruleus neurones that have matured in the eye can reinitiate extensive fibre growth in response to contact by a graft of denervated iris tissue, but not following contact with a host iris that still has innervation¹⁰. In these studies denervation was seen to be the important factor in stimulating fibre outgrowth from the *in oculo*, mature locus coeruleus neurones. Similarly, caudate denervation may act to stimulate fibre outgrowth from the fimbria.

Our finding that disturbed but non-lesioned nerves in brain can be induced to grow is very similar to results obtained by Cajal in the young cat after spinal cord damage⁹. In fact, the presence of axonal varicosities, as we observed in our AChE-stained fibres, was noted by Cajal to occur in regrowing spinal nerve fibres. Speidel reported collateral growth in normal peripheral nerves of the tadpole¹¹. These nerve fibres sometimes formed entirely new pathways, induced by the denervation of a nearby region. Speidel also noted that this type of axonal growth seemed to be characteristic of unmyelinated axons. In this respect, Svendgaard *et al.*⁴ have suggested that the unmyelinated fibres of the fimbria have an ability to regenerate that may be shared by all unmyelinated axons in the central nervous system. They report a regenerative capacity of these nerves, although disturbance-induced growth (and not axotomy-induced growth) of the cholinergic fimbrial fibres could also account for their observations. Instances of neuronal remodelling that occur following regeneration, sprouting and growth evoked by mechanical perturbation as described here, may all rely on similar growth-inducing factors.

Our findings suggest that the consequence of denervation can extend beyond the immediate vicinity of damage and apparently stimulate the growth of axonal branches over a

Fig. 3 *a*, Photomicrograph of AChE-positive axonal varicosities in fimbria branch 32 d after cotton swab-NaCl treatment of the fimbria. In cresyl-violet stained material these varicosities did not exhibit any staining. *b*, Photomicrograph of AChE-positive axonal varicosities 11 d after cotton swab treatment of the fimbria. Scale bar, 50 μ m.

distance a few millimetres from the denervated zone. This growth can apparently be initiated by several seemingly nonspecific mechanical disturbances of these nerves. Axonal growth from the fimbria may provide an opportunity to study the factors that effect initiation, stimulation and guidance of growing nerve fibres in the mature mammalian brain.

Positive inotropism of vanadate in cat papillary muscle

MANY samples of 'Sigma grade' ATP from Sigma Chemical Co. reportedly contained an impurity which induces anomalous kinetics of (Na, K)-ATPase activity¹⁻³. This impurity has recently been identified as vanadate⁴, and shown to inhibit (Na, K)-ATPase from kidney⁴ and red blood cells⁵. These findings have received considerable interest because of a possible physiological role of vanadate as an endogenous regulator of (Na, K)-ATPase activity³⁻⁵. We now report that vanadate is capable of producing positive inotropic effects in electrically driven papillary muscles isolated from cats.

Cats (0.5-1.6 kg) were anaesthetized with sodium pentobarbital (30 mg per kg i.p.) and papillary muscles (mean cross-sectional area $0.62 \pm 0.05 \text{ mm}^2$, $n = 17$) were dissected from the right ventricles. The preparations were attached to a platinum stimulating electrode and mounted individually in glass tissue chambers for recording isometric contractions as described previously⁶. The bathing solution (5 ml) containing (mM) NaCl 136.9, KCl 5.4, CaCl₂ 1.8, MgCl₂ 1.05, NaH₂PO₄ 0.42, NaHCO₃ 11.9, glucose 5.5 was equilibrated with 95% O₂ + 5% CO₂ and maintained at 35°C. The preparations were driven electrically at a frequency of 0.2 Hz (duration 5 ms, intensity about 10% above threshold). Drugs used were ammonium vanadate anhydrous (NH₄VO₃), sodium vanadate anhydrous (NaVO₃; both from Merck, Darmstadt) and ($\pm$)propranolol HCl (ICI). The compounds were freshly dissolved in bathing medium and injected into the tissue chamber in volumes of 300 μ l or less. NH₄VO₃ and NaVO₃ did not contain any measurable calcium and did not change the pH (7.4) of the bathing solution.

The effects of NH₄VO₃ on force of contraction are illustrated by the representative experiment shown in Fig. 1. NH₄VO₃ (20-500 μ M) was added cumulatively, and the time of exposure

Fig. 1 Effect of NH₄VO₃ on isometric force of contraction of a cat isolated papillary muscle driven electrically at a frequency of 0.2 Hz. NH₄VO₃ was applied cumulatively at concentrations of 20-500 μ M as indicated. The time of exposure to each concentration of NH₄VO₃ was about 15 min. After exposure to 500 μ M NH₄VO₃, the preparation was washed three times with drug-free bathing solution. Temperature 35°C. Extracellular Ca²⁺ concentration 1.8 mM. Preparation diameter 0.7 mm. Experiment 13 06 784. Similar results were obtained in each of nine other preparations.

to each concentration was about 15 min. NH₄VO₃ produced a concentration-dependent increase in force of contraction. The effect became clearly visible at 50 μ M and was maximal at 500 μ M. These concentrations correspond to those of Na₂VO₄ required to inhibit rubidium uptake in intact red cells by 50 to 80%⁵. The typical time course of action is also well shown. An increase in force of contraction was detectable after about 1 min, and a peak effect was attained after 6-3 min. The effect of NH₄VO₃ was readily reversible within less than 15 min on washing with drug-free bathing solution. Higher concentrations of NH₄VO₃ (1 mM) produced arrhythmias as a sign of toxicity.

The mechanism of the positive inotropic effect of NH₄VO₃ remains to be elucidated. Similar results as with NH₄VO₃ were obtained with NaVO₃ and, moreover, the effect of NH₄VO₃ was also observed in the presence of 1 μ M of the β -adrenoceptor blocking agent propranolol (data not shown). This indicates that the positive inotropic action of NH₄VO₃ was neither due to an effect of the NH₄⁺ ion nor to a stimulation of β -adrenoceptors. Experiments are in progress to determine whether the positive inotropic effect of vanadate is accompanied by an inhibition of myocardial (Na, K)-ATPase, and, if so, whether both effects occur at similar concentrations of vanadate.

-1	0.220	1.06, 1.06 ^g , 1.06 ^c , 1.06 ^h , 1.09
-2	0.027	1.16
Others		0.98, 1.04, 1.12

*Frequency values given are pooled frequencies of the individual variants as given by Prakash¹⁶.

non-standard electrophoretic conditions^{11,13}, only two, 1.00^c and 1.00^e, were resolved from the other variants in their standard classes by isoelectric focusing. One of these, 1.00^c, which is separable from other 1.00 variants by its slower mobility on 14% starch gel at pH 6.8 (ref. 11), occupied the same position as the 0.94 variant on isoelectric focusing.

Esterase-5 is a dimeric enzyme and the positions of some heterodimers are depicted in Fig. 1. Heterodimers are formed readily during electrophoresis of mixtures of homodimers. The 0.97 M variant behaves as a monomer in all conditions, and does not form stable heterodimers with the subunits of other variants.

The position of most variants after isoelectric focusing can be interpreted in terms of the charge-state model (Table 1). There are five main charge classes characterised by an essentially equal spacing. Three variants (0.98, 1.04, 1.12) exhibit very anomalous behaviour on isoelectric focusing and also do not fit the proposed charge classes; they are discussed below. The positions of the 1.16/1.00 and the 1.06/0.94 heterodimers show that these four variants are separated by equal charge changes. We propose that this is the result of substitutions which are approximately one unit charge jump apart. Small variations in charge are observed between the variants within single charge classes, but these variations in charge are small compared to the postulated unit charge jump. The apparent charge identity after isoelectric focusing of variants, which can be distinguished by standard conditions of electrophoresis (such as 1.06 and 1.09), suggests that differences due to apparent conformational changes are being detected by standard electrophoresis. Shifts in relative mobility could also represent small changes in net charge between variants being differentially expressed at the different pH conditions of electrophoresis.

The pooled frequencies of the variants within each major charge class fit a charge class configuration expected for neutral alleles with the central classes being most frequent (Table 1).

As pointed out above, the 1.00^c variant is not resolved from the 0.94 variant using isoelectric focusing. It is postulated that a substitution, resulting in an extra histidine residue, separates this variant from the other 1.00 variants. At the isoelectric point for *Est-5* (approximately pH 5.0), the 1.00^c variant would then jump charge classes; the size of this jump is consistent with our postulated unit charge change.

Considering their relative positions on isoelectric focusing, three variants (0.98, 1.04 and 1.12) display much faster mobilities in standard electrophoretic conditions than would be expected from their charges. These three variants lie approximately halfway between the postulated charge classes. They are evenly spaced and show the same charge jump increment as the major charge classes. These results suggest that they differ from each other by single charge changes, and may possess common features which separate them, as a group, from the variants which form the major charge classes.

Johnson¹⁴ has examined the charge-state model for *Est-5* indirectly by the use of gel-sieving. He claims that the combination of the free electrophoretic mobilities and retardation effects coincidentally result in apparent unit increments in mobility at pH 8.9. He concluded that the seven variants which he examined fit a charge class configuration; however, he did not study a

Fig. 2 Top: electrophoresis of (0.89, 0.94, 1.00^c, 1.00, 1.02, 1.06 and 1.09) *Est-5* variants in 5% acrylamide gel pH 8.9 (ref. 9). Bottom: isoelectric focusing of (0.89, 0.94, 1.00^c, 1.00, 1.02, 1.06 and 1.09) *Est-5* variants. Isoelectric focusing was based on the method of Vesterberg¹⁷, using 5% gels, 18 × 18 cm, polymerised by ammonium persulphate. Gels contained 1.6% w/v pH 4–6 and 0.4% w/v pH 3–10 ampholytes. Electrodes of Pt wire between Whatman 3MM paper were 16 cm apart; anodic and cathodic solutions were 0.2% v/v sulphuric acid and 0.4% v/v ethanolamine respectively. Samples, 10–15 μl, were loaded on 5 × 5 mm Whatman 3MM paper placed 2 cm from the cathode. Electrophoresis was at 4 °C for 4 h.; the voltage was gradually raised to 500 V over 1 h and maintained at this value. pH measurements were made at 20 °C on ampholytes eluted from transverse sections of gel. Staining for esterase activity was by the standard method¹³.

number of fairly common variants of intermediate mobility. Johnson claimed to find extensive genetic heterogeneity within allelic classes. He also found allelic heterogeneity in certain strains (some believed isogenic), yet no heterozygotes were found in these strains, which seems unlikely. More recently, Cobbs and Prakash¹⁵ examined the fit of *Est-5* to a charge state configuration using gel-sieving, and by chemically modifying the charge on several reference proteins. Using the average change in mobility of each reference protein per unit change in charge, they estimated an overall average mobility change per unit charge of 0.046 ± 0.029 . Chemical modification of charge on *Est-5* was not carried out. They assumed that the overall average was applicable to *Est-5*. As the magnitude of each charge change will vary with protein size and the proportion and balance of its charged residues, we consider it fortuitous that their estimate derived from diverse proteins was so close to our postulated unit charge change. The results of the studies by

Johnson¹⁴, and Cobbs and Prakash¹⁵, both using indirect methods of charge estimation, are incompatible with each other, and with the results of this study.

Our study of the differences in charge balance between *Est-5* variants shows clearly that *Est-5* can be fitted to the charge-state model. Despite the large numbers of *Est-5* variants segregating in natural populations, the total variability collapses into two offset charge class configurations, of five and three classes. There does not seem to be a continuum of charge change as claimed by Johnson⁶, but rather a clustering of charge variants around unit charge increments. Electrophoretic variation within charge classes and between the two major charge configurations may be the result of conformational differences exposed on electrophoresis. Our study indicates that conventional electrophoresis, in different conditions, will reveal considerably more genic variability than the simple charge heterogeneity shown by isoelectric focusing. Nevertheless, allelic variation at a complex locus such as *Est-5*, can be more clearly understood by the application of isoelectric focusing. Experiments are in progress to determine the structural basis for the differences between various *Est-5* variants.

Bile salt sensitivity of *Escherichia coli* χ 1776

Escherichia coli χ 1776¹, a 'biologically contained' (EK2) host specifically constructed for genetic manipulation (ref. 1 and R. Curtiss, III, personal communication) contains many mutations which decrease its survival characteristics compared with wild-type *E. coli* and which also prevent its colonisation of the intestinal tract of mammals. The bile salt sensitivity of χ 1776 is one of the parameters which preclude its survival in the intestine. This sensitivity is related to modifications of the cell envelope structure but, more specifically, to mutations at the *oms-1* or *rfb-2* loci. Curtiss (personal communication) has reported that the reversion frequency of χ 1776 to bile salt resistance is approx. 10^{-7} to 10^{-9} . However, the cell surface structures of bacteria are subject to phenotypic variation and under control of a number of genes. In this paper we describe experiments which indicate that the bile salt sensitivity of χ 1776 is phenotypically variable.

Batch cultures of χ 1776 in L broth were monitored for bile salt resistance at 16 and 40 h after the initiation of growth. The number of bile salt-resistant organisms detected was constant,

Table 1 Bile salt resistance of χ 1776 in batch cultures

Inoculum size per 100 ml culture	Time after inoculation (h)	Proportion of resistant organisms	Culture pH
5×10^7 organisms	16	1 in 10^4 - 10^5	6.5
5×10^7 organisms	40	1 in 10 - 10^2	8.0
10^9 organisms	16	1 in 10 - 10^2	8.0

χ 1776 was grown in L broth (1% Bacto-Tryptone, 0.5% yeast extract, 0.5% NaCl, 0.1% glucose, supplemented with 0.01% diaminopimelic acid, 0.004% L-threonine, 0.001% L-methionine, 0.0001% biotin and 0.004% thymidine). The initial pH of the culture medium was adjusted to 7.0 by addition of 1 M NaOH. The bile salt sensitivity of different cultures of χ 1776 was monitored by plating out duplicate samples (0.2 ml) on L-agar and MacConkey agar supplemented with the specific growth requirements of the strain as given above. Essentially identical results were obtained with supplemented MacConkey agar plates containing 0.15% (Difco and Oxoid no. 3 formulations) and 0.5% (Oxoid no. 5 formulation) bile salts.

within experimental error, over a number of experiments but was dependent on the time of incubation at 37°C, the initial inoculum size and the final pH of the culture supernatant (Table 1).

The variation in the culture pH indicated that the organism initially utilised the glucose present (0.1%) to produce acid. Depletion of glucose resulted in the utilisation of amino acids as carbon sources and in an increase in culture pH due to the secretion of ammonia. Differences in the numbers of bile salt-resistant organisms found here in primary cultures (low inoculum sizes and short incubation times) and those found by Curtiss (1 in 10^7 - 10^9) may be due to differences in the batches of medium used. Nevertheless, these results indicate that the bile salt sensitivity of χ 1776 is dependent on culture conditions and that the surface properties of this organism might be subject to phenotypic change. The effect of growth rate on the bile salt sensitivity of χ 1776 was therefore investigated in an attempt to gain further information. This was of additional interest as the mean generation time of *E. coli* in the mammalian intestine is considerably longer (12-24 h) than that observed using conventional laboratory techniques (0.5-1.5 h)^{3,4}.

A chemostat culture was set up so that χ 1776 could be grown at a very low rate (Table 2). When steady-state conditions were reached (5 d) the culture was shown to be glucose limited (that is no glucose was present in the culture supernatant and addition of glucose to the chemostat produced a corresponding increase in cell density); the culture pH was uncontrolled and was 8.2. One in two of the organisms present were bile salt-resistant in these conditions. The dilution rate was then increased and at each steady state the number of bile salt-resistant organisms and the pH of the culture was measured. The proportion of bile salt-resistant organisms present in these different conditions remained approximately constant even though the culture pH, as expected, fell as the dilution rate increased (Table 2). This indicated that a bile salt-resistant variant had been selected.

In an additional experiment a chemostat culture of χ 1776 was grown to steady-state conditions at a dilution rate of 0.025 h^{-1} , the culture pH being maintained at 6.0 by addition of 2 M HCl. The bile salt resistance of this culture remained at its starting level of 1 in 10^4 . The culture pH was then adjusted to 8.0 by addition of 2 M NaOH and the bile salt resistance monitored as a function of time. In less than one mean generation time, one in four of the organisms present had become bile salt resistant. This rate of change in the population in the chemostat indicates that the bile salt sensitivity of χ 1776 is subject to phenotypic variation. After 10 d (during which the proportion of resistant organisms remained at one in four) the culture was returned to pH 6.0 by addition of 2 M HCl and a new steady state was established. Approximately one in ten organisms in the culture remained bile salt resistant, indicating that selection of a resistant variant had again occurred and that this variant was rela-

tively stable. The growth of a single colony isolate of the bile salt-resistant variant in batch culture confirmed this stability. The variant grew well at pH 8.0, 7.1 and 6.3 in the presence of at least 0.25% bile salts and in the presence of nalidixic acid $50 \mu\text{g ml}^{-1}$. Furthermore, growth at pH 8.0 in the absence of bile salts produced a culture in which less than one in 10^4 organisms were bile salt sensitive. This increased to approximately one in 2×10^2 when the variant was grown at pH 6.3.

Throughout these experiments, lasting a number of mean generation times, no variation in the absolute requirements for diaminopimelic acid and thymidine were observed. Indeed, the cultures remained phenotypically $\chi 1776$ except for the variations detected in bile salt sensitivity. There had therefore been no contamination with other *E. coli* strains.

Table 2 Bile salt resistance of $\chi 1776$ in chemostat cultures

Dilution rate	Mean generation time (h)	pH of culture	Proportion of resistant organisms
Initial batch culture	1 (in log growth)	7.0 → 6.5	1 in 10^4
0.025	26	8.5	1 in 2
0.05	13	8.2	1 in 5
0.1	7	7.7	1 in 5
0.3	2	7.5	1 in 10
0.6	1.1	6.4	1 in 10
Wash-out point			

A Porton-type chemostat (500 ml L broth containing 0.1% glucose and growth supplements) was inoculated with $\chi 1776$ and this was grown at 37°C in batch culture conditions; after 16 h the chemostat was switched to the continuous culture mode with the dilution rate set at 0.025 h^{-1} (mean generation time 26 h). The pH was monitored but not controlled. The dilution rate was then increased and the number of bile salt-resistant organisms was determined at each new steady state. The culture density remained at approximately 5×10^9 – 10^{10} organisms ml^{-1} until wash-out.

These experiments do not necessarily preclude the use of $\chi 1776$ as a host in genetic manipulation. They do, however, show that, if care is not taken, selection for variants of this organism may occur. These variants, with slightly better growth characteristics, can quickly outgrow 'authentic' $\chi 1776$ produced by serial passage in batch cultures. In addition, bile salt-resistant variants of $\chi 1776$ have slightly better survival characteristics in animal tests and are better recipients for some conjugative plasmids (R. Curtiss, III, personal communication). These results indicate that any form of biological containment that is dependent on the surface properties of *E. coli* may be suspect.

Finally, and more importantly, these experiments demonstrate the need to monitor the safety features of any 'biologically contained' organism before, and during any genetic manipulation experiment.

Expression of λ red genes restores *recB*-dependent protein X induction in *E. coli*

DNA DAMAGE and/or inhibition of DNA synthesis elicit a number of responses in *Escherichia coli* known as SOS functions¹, including the production of large quantities of a protein provisionally called protein X (ref. 2). Induction of protein X, like the other SOS functions, requires functional *recA* and *lexA* genes^{3,4}. Gudas and Pardee⁴ proposed a model to suggest roles for *recA* and *lexA* in the regulation of protein X production. Several research groups have identified protein X as the *recA* gene product^{5–8} which prompted them to formulate updated models, to account for the apparent autoregulation of the *recA* gene^{6–8}. These models propose that the *lexA* gene codes for a repressor which inhibits the transcription of the *recA* gene. Following treatment, such as exposure to ultraviolet irradiation or nalidixic acid, a small inducer molecule is produced that causes the *recA* gene product, present in low levels in untreated cells, to inactivate the *lexA* repressor. This allows transcription of the *recA* gene that results in the production of large amounts of the *recA* gene product, protein X. Gudas and Pardee⁴ suggested that the inducer molecule may be a DNA degradation product resulting from the action of the *recBC* gene products, exonuclease V. In support of this idea they showed that protein X is not induced by nalidixic acid in *recB*[–] mutants deficient in exonuclease V. On the other hand, Little and Hanawalt⁹ showed that intracellular degradation of unmodified phage DNA by restriction is not sufficient to induce protein X, and they have challenged the role of DNA degradation in the induction process. In this report we show that phage λ genes controlling λ exonuclease can restore the missing function for the induction of protein X in *recB*[–] mutants. This is further evidence that DNA degradation is required to derepress the *recA* gene.

As the exonuclease V protein has an ATPase activity in addition to both endo- and exonuclease activities¹⁰, the missing function for the induction of protein X in nalidixic acid-treated *recB*[–] mutants could be some function other than that of degrading DNA. We have therefore tried to determine whether λ exonuclease, an exclusively exonucleolytic enzyme¹¹, could circumvent the *recB* mutation in the induction of protein X. To do this we have determined whether protein X was induced in *recB*[–] lysogens that were transiently induced to produce λ exonuclease before treatment with nalidixic acid. In similar experiments others have shown that transient prophage induction enhanced *recB*-dependent cell survival after ultraviolet¹² or X-ray irradiation¹³.

Figure 1 shows the effect of transient heat induction of λ cI857 prophage on protein X induction in nalidixic acid-treated *recB*[–] lysogens. Lanes 8–12 show that the amount of protein X increased with increasing times of incubation of 42°C . In control experiments shown in lanes 3 and 4, neither a 5-min incubation at 42°C nor nalidixic acid treatment alone was sufficient to induce protein X. To investigate the role of λ exonuclease in this induction, the above experiments were repeated using *recB*[–] lysogens carrying prophage with mutations in genes controlling λ exonuclease activity. The combined treatment of heat induction and exposure to nalidixic acid was not sufficient to induce protein X when the prophage carried the mutations *redX314*, (lane 6) or *redB113* (lane 7). *redX314* and *redB113* are point mutations in the genes which code for λ exonuclease and β protein, respectively^{14,15}. λ exonuclease acts primarily at 5'-phosphoryl termini on double-stranded DNA molecules, and the only acid-soluble products are deoxyribonucleoside 5'-monophosphates¹¹. The *redX314* mutation decreases the activity of λ exonuclease to less than 2% of normal activity¹⁴. Although the *redB113* mutation does not affect the λ exonuclease enzyme, it does alter the antigenic properties of the

Fig. 1 Strain AB2470 *recB21* (ref. 21) was lysogenized with λ CI857, λ CI857 *redX314* or λ CI857 *redB113*. The λ CI857 mutant produces a temperature-sensitive repressor. The *redX314* and *redB113* mutations are described in the text. Lysogens were grown at 30 °C to an $A_{590} = 0.2$ in glucose-M9 media containing required amino acids and thiamine; 1-ml samples were incubated at 42 °C for various times before addition of nalidixic acid, 50 $\mu\text{g ml}^{-1}$ (Sigma). At 30 min after addition of the drug, ^{14}C -leucine (Schwarz-Mann) was added (to 5 $\mu\text{Ci ml}^{-1}$) and incubation was continued for 60 min at 30 °C. The cells were collected by centrifugation and prepared for SDS-polyacrylamide gel electrophoresis as described by Little and Hanawalt⁹. This figure is a composite picture of autoradiographs of two slab gels. Equal amounts of radioactivity were added to each slot in each gel. All lanes except 6 and 7 show proteins synthesised in AB2470 carrying λ CI857 prophage, unless otherwise noted, that were treated as described below. Untreated (lane 1); irradiated with 30 J m^{-2} UV (lane 2); incubated at 42 °C for 5 min (lane 3); exposed to nalidixic acid, 50 $\mu\text{g ml}^{-1}$ (lane 4); incubated at 42 °C for 5 min followed by exposure to nalidixic acid (lane 5); AB2470 (λ CI857 *redX314*) treated as in lane 5 (lane 6); AB2470 (λ CI857 *redB113*) treated as in lane 5 (lane 7); incubated at 42 °C for 1 min (lane 8), 2 min (lane 9), 3 min (lane 10), 4 min (lane 11) and 5 min (lane 12) followed by exposure to nalidixic acid.

β protein¹⁵. The only known activity of the β protein is to enhance the affinity of λ exonuclease for DNA *in vitro*¹⁶. This evidence indicates that the activity of λ exonuclease is responsible for the induction of protein X in nalidixic acid-treated *recB*⁻ lysogens. We interpret this to mean that DNA degradation is necessary for nalidixic acid-mediated induction of protein X.

As SOS functions, such as cell filamentation, error-prone DNA repair, and λ prophage induction, are dependent on the *recA*⁺ *lexA*⁺ genotype, the derepression of the *recA* gene seems to be necessary for their expression. For this reason, SOS functions are elicited by treatments that result in DNA degradation. How does the *recA* protein activate SOS functions? Roberts and Roberts¹⁷ have shown that λ prophage induction is due to a *recA*-dependent proteolytic cleavage of the λ repressor. They have recently found that the *recA* gene product, protein X, cleaves the λ repressor *in vitro* (J. W. Roberts, personal communication). Witkin¹⁸ proposed that all of the SOS functions are derepressed by a common mechanism, is by proteolytic cleavage of the repressor(s) controlling the SOS operon(s). DNA degradation, an initial consequence of DNA damage or of a stalled replication fork, may provide a primary danger signal which is amplified through the action of the *recA* protein resulting in the expression of a set of functions designed to enhance cell survival.

Although the above evidence clearly indicates that *recB*-dependent DNA degradation is required for nalidixic acid induction of protein X, this dependence may not apply to induction by other agents. For example, lane 2 of Fig. 1, indicates that ultraviolet induction of protein X is independent of the *recB* mutation, confirming the results of Little and Hanawalt⁹. Perhaps excision of ultraviolet photoproducts or post-replication repair results in sufficient DNA degradation, not requiring the *recBC* exonuclease, to trigger the derepression of the *recA* gene. In support of this suggestion, Braun¹⁹ has shown that ultraviolet induction of λ prophage does not occur if both excision and replication are eliminated genetically. Thus, we propose that more than one pathway of DNA degradation may lead to the induction of SOS functions.

What is the identity of the inducer? An attractive idea is that a modified DNA degradation product serves as a specific signal to communicate to the cell that its genetic material is in jeopardy, and that the SOS functions are needed. This would explain the results of Little and Hanawalt⁹ that degradation of unmodified phage DNA is not sufficient to cause induction. As modification is a post-replication process²⁰, a modified DNA degradation product could unequivocally be distinguished from DNA precursors normally present in the cell. Moreover, such a role for modification in the induction of SOS functions would emphasise the importance of pathways for the preservation of genetic material and would provide considerable insight into the cellular function of DNA modification.

Haem exposure as the determinate of oxidation-reduction potential of haem proteins

KASSNER¹ has proposed that the apolarity of the haem environment primarily determines the oxidation-reduction potential, E'_0 pH 7.0, of a haem protein. Since high resolution crystallographic models are now available for six haem proteins with E'_0 values of between 20 and 320 mV, I have tested the Kassner proposal by comparing the kinds of atoms contacting the haem in each of these proteins. The results demonstrate that the apolarity of the total haem environment for these proteins is virtually identical but that the E'_0 value is inversely dependent on the exposure of the haem to an aqueous solvent.

Surface area calculations were made using a DEC PDP 11/45 computer and protein coordinates supplied by the Brookhaven Protein Data Bank. An unpublished computer program developed by Arnone and Briley (similar to that of Shrake and Rupley²) to both generate and display protein surfaces accessible to water solvent molecules was used. Each atom in a protein is represented by a sphere centred about its atomic coordinates with radius the sum of its Van der Waals radius and 1.4 Å, the radius of a water molecule. A three-dimensional grid of equally spaced points is constructed large enough to envelop the entire hydrated protein molecule. Grid points which lie within the space defined by spheres centred at each atom are termed interior points. The six nearest neighbours of each interior point are then examined. Those interior points which are not bounded on all sides by other interior points are identified as surface points. Calibration experiments have shown that the accessible surface of a sphere representing a typical hydrated protein atom is sampled by about 300 points using a 0.5 Å grid and results in a random calculation error of less than 5%. All surface points which lie on the surface of only one atom are assigned to that atom, while surface points shared by more than one atom are uniquely assigned to the atom having the nearest centre. The total number of surface points associated with each atom is converted to Å² of surface area using the factor 3.41 surface points Å⁻² obtained from a calibration curve. Carbon and sulphur atoms are considered as apolar atoms while all other haem protein atoms are considered as polar atoms.

All surface area calculations reported here were made using a 0.5 Å grid. The surface area of each haem and each apoprotein

was obtained by elimination of all coordinates associated with the apoprotein and the haem atoms, respectively, prior to calculation. The surface area of each haem crevice was calculated by insertion of the haem surface into the protein surface, removal of all points common to this composite surface and to the haem protein and assignment of the points remaining to individual atoms as above.

The total accessible surface area of the crystallographic model for each of the six haem proteins considered is listed in Table 1, entry 1. These surface areas are related to molecular weight by the expression, surface area = $11.0 M^{2/3}$, in excellent agreement with the equation developed by Teller³ using the surface areas calculated for proteins by the procedure of Lee and Richards.⁴ Approximately half ($53 \pm 3\%$) of the accessible surface area of these haem proteins is contributed by apolar atoms, entry 2, a percentage within the range calculated for five proteins by Lee and Richards³ and by Shrake and Rupley². These favourable comparisons indicate that our procedures for calculations of surface area and assignment of area to individual atoms are consistent with results obtained by others.

Removal of the coordinates for the apoprotein atoms from each of the haem proteins and subsequent surface area calculation, entry 4, indicates that a haem constructed from protoporphyrin IX has an accessible surface area of 805 ± 15 Å². As shown in Table 1, entry 3, between 77 and 96% of haem surface is buried in the haem proteins considered. Inspection of the haem atoms which are accessible in the haem proteins indicates (1) that neither the iron atom nor any of the pyrrole or methine bridge atoms are accessible, (2) that the atoms comprising some of the methyl, vinyl and propionate side chains are accessible, and, (3) that the haem is orientated in these haem proteins in one of two distinctive modes exposing different side chains as illustrated in Fig. 1. Haems which are not covalently attached to the polypeptide chains as in haemoglobin, myoglobin and cytochrome *b₅*, are orientated such that the side chain pyrrole rings 3 and 4 are accessible to the solvent, presumably to place the propionate carboxylates in a more polar environment. By contrast, haems which are covalently attached to polypeptides by addition of cysteinyl sulphhydryl groups across vinyl side chains, as in the cytochromes *c*, appear to be rotated by about 90° exposing the vinyl group of pyrrole 2 and the methyl groups of pyrroles 2 and 3. This orientation which buries the two propionates, would be expected to require complementary pairing of the buried carboxylate oxygen atoms by polar atoms in the haem crevice.

Table 1 Accessible surface area calculations of haem proteins

Entry	Parameter	Cyto <i>c</i> ₂	Cyto <i>c</i>	Cyto <i>c</i> ₅₅₀	Hb _α	Hb _β	Myo	Cyto <i>b</i> ₅

Reduction potential								
12	E'_0 , pH 7 (mV)	320 ⁶	260 ⁷	250 ⁸	113 ⁹	53 ⁹	47 ^{9,10}	20 ¹¹

The protein column headings reading from left to right refer to cytochrome *c*₂ from *Rhodospirillum rubrum*, ferricytochrome *c* from tuna heart, cytochrome *c*₅₅₀ from *Paracoccus denitrificans*, the α₁ subunit of human deoxyhaemoglobin, the β₂ subunit of that protein, sperm whale metmyoglobin, and cytochrome *b*₅ from bovine liver. Surface areas are expressed in Å².

Fig. 1 Haem orientations in haem proteins. The haem present in haemoglobin, myoglobin and cytochrome *b*₅ is represented on the left and the haem in cytochrome *c* on the right. The pyrrole rings represented by circles numbered 1-4 and the pyrrole side chains represented by M, V and P for methyl, vinyl and propionate groups, respectively. Each haem is orientated such that its exposed side chains are at the bottom. The mean percentile exposure and standard deviation for the exposure of haem atoms in the haem proteins relative to their exposure in haem itself are listed below the atoms concerned. A, B, C and O refer to the exposure of the carbon atoms, A-C, and the oxygen atoms, O, of methyl, vinyl and propionate groups reading outwards from the pyrroles considered.

As shown in Table 1, at least 98% of the total accessible surface area for each haem, entry 4, can be accounted for by the sum of its accessible surface area in the haem protein, entry 3, and the accessible surface area of its crevice, entry 5. More than half, 61 ± 15%, of the crevice polar surface is contributed by polypeptide backbone oxygen and nitrogen atoms. By contrast, only 8 ± 3% of the crevice apolar surface is contributed by polypeptide backbone carbon atoms. No good correlation exists between the E'_0 value and the percentage contribution of the atoms of any amino acid or groups of amino acids, for example aromatic apolar atoms, entry 10, to either the polar or apolar crevice surface. The apolar side chain atoms of Phe, Ile, Leu and Val residues contribute at least 50% of the crevice apolar surface while those of Asp, Glu, Asn, Gln and Arg contribute less than 8% in keeping with the occurrence of these residues in protein interiors⁵.

Fig. 2 Dependence of reduction potential, E'_0 , on the per cent exposure of the haem (○), on the per cent apolarity of the haem crevice (●) and on the per cent apolarity of the haem environment (●). All values were obtained from Table 1. Each line represents a least squares analysis of the values shown.

The dependence of the reduction potential on the haem exposure, on the apolarity of the haem crevice and on the apolarity of the haem environment (Table 1, entries 8, 9, and 11) are compared in Fig. 2. The burial of the haem is accompanied by a nearly parallel decrease in the apolarity of the haem crevice. This parallelsim seems reasonable since burial of one or both haem propionates and/or provision of the second extrinsic haem ligand by the protein would require complementary polar atoms in the haem crevice as noted above. The net effect of these parallel changes is to maintain the apolarity of the haem environment constant while the reduction potential varies by 300 mV as shown in Fig. 2. This observation is clearly contrary to the Kassner proposal.

As shown in Fig. 2, the reduction potential is inversely related to the fraction of haem surface exposed according to the expression $E'_0 = -15 (\% \text{ exposure}) + 345 \text{ mV}$. This empirical relationship may reflect the accessibility of the haem to environmental O_2 or the proximity of the extrinsic ligands to the haem iron. As more of the protein envelops the haem, the ferrohaem would be more protected from oxidants and/or the haem iron-extrinsic ligand bond distance would be diminished. Both of these changes should increase the reduction potential of a haem protein¹².

The equation relating E'_0 and haem exposure merits additional comment. This equation predicts that a totally exposed haem would have an E'_0 value of -1,155 mV and that a totally buried haem a value of +345 mV. This range encompasses the E'_0 values reported^{13,14} for the majority of haem proteins except for cytochrome oxidase, cytochrome *f* and a few cytochromes *c*₅₅₃ and *c*₅₅₂, whose values extend to +400 mV. The equation is inappropriate for cytochrome oxidase since its haem moiety, haem A (ref. 15), has a larger surface area due to the presence of a farnesyl side chain. A very modest increase in the slope of the line shown in Fig. 2 would raise the maximum E'_0 value to +400 mV and thus accommodate the remaining measured values. Unfortunately, the E'_0 value for a monomeric haem in aqueous solution cannot be measured experimentally since haems avidly polymerise by base stacking and/or micelle formation. The E'_0 value for the monomeric haem octapeptide of cytochrome *c* has been reported¹⁶ to be -217 mV. The equation predicts that about 37% of the surface of this haem would be buried by the peptide atoms. While the structure of the haem octapeptide is unknown, a CPK model indicates that the predicted burial is feasible. Thus, the exposure of the haem moiety, rather than the apolarity of the haem environment or the ligands in the fifth and sixth haem coordination position seems to be the principal determinant for the magnitude of the E'_0 value.

This investigation was supported by a USPHS grant GM-13215 from the Institute of General Medical Sciences. I thank Arthur Arnone, Patrick Briley and Charles Swenson for useful discussions.

MOLECULAR ORBITAL THEORY

An Introductory Lecture Note and
Reprint Volume

C. J. Ballhausen and H. B. Gray

"A very concise exposition of the applications of molecular orbital calculations to inorganic chemistry... Suitable for grad students and advanced undergrads interested in the theory of structure... As a unique feature, the last half of the book consists of a reprint collection of eleven papers pertaining to the field."

Choice

Contents: Atomic Orbitals. Diatomic Molecules. Electronic States of Molecules. Hybridization. Band Intensities. Triatomic Molecules. Selected Molecules with Four or More Atoms. Molecular Orbitals Involving d Valence Orbitals. Appendixes. References. Problems. Index.

1964 (5th printing, 1978), xii, 274 pp.
Pbk. 0-805-30451 \$9.50

COMPLEX CARBOHYDRATES Their Chemistry, Biosynthesis, and Functions

A Set of Lecture Notes

Nathan Sharon, *The Weizmann Institute of Science*

"... a detailed, up-to-date review on the chemistry, biosynthesis, and functions of glycopeptides and glycoproteins... Professor Sharon's style of writing is easy to follow; his explanation is lucid; and his enthusiasm for the subject adds to the quality of the text."

Journal of Chemical Education

INTRODUCTION to STEREOCHEMISTRY

Kurt Mislow, *Princeton University*

This short text provides a sufficient background for the student to solve independently most of the complex problems in this area of organic chemistry. Each section is followed by about 20 questions and problems which are designed not only to test understanding but to advance the student beyond the descriptive material. Answers to exercises are provided.

Contents: Structure and Symmetry. Stereoisomerism. Separation and Configuration of Stereoisomers. Bibliography. Index.

1965 (7th printing, 1978), xii, 194 pp., illus.
Pbk. 0-805-37101-X \$11.50

SECOND EDITION, revised, enlarged, reset INTERPRETATION of MASS SPECTRA

An Introduction

F. W. McLafferty, *Cornell University*

"This is an uncommon book. In addition to being a first-rate scientific document and text, it is a highly personal expression. Every page is colored by the author's enthusiasm, by his style in dealing both with chemical concepts and with his students and associates; it sometimes seems as though he is a part of his own subject matter... From the first page of the preface through the detailed solutions to unknowns, the book conveys McLafferty's sense of excitement and fun in working with mass spectra."

Journal of Chemical Education

Contents: Introduction. Elemental Formulas. The Molecular Ion. Ion Fragmentation Mechanisms. Postulation of Molecular Structures. Mass Spectra of Common Compound Classes. Auxiliary Techniques. Unimolecular Ion Decomposition Reactions. Solutions to Unknowns. References. Appendix. Index.

1973 (5th printing, 1978), xx, 278 pp., illus.

NEW YORK, N.Y. 10017

Aims and Scope

The journal will be primarily concerned with the publication of ethological and sociobiological data and theories presented as descriptive studies, experiments, literature reviews, or in papers dealing with theory development and refinement. As the primary focus of the journal is on the human species, the aim is to foster the dissemination of scientific knowledge in ethology, sociobiology, and closely related fields, particularly as this knowledge applies to humans. Findings and theories largely concerned with nonhuman species will be acceptable to the journal provided the human implications are specified.

reviews

Prehistoric standing stone sites

E. MacKie

Sun, Moon and Standing Stones. By J E Wood Pp 217. (Oxford University Press: Oxford, 1978) £6.95.

For some time now there has been a clear need for a book which presents the findings of the 'archaeoastronomers'—and this means mainly Professor Alexander Thom and his family—on the British prehistoric standing stone sites to the informed general public (an audience which, in this particular case, includes much of the archaeological profession). Thom's discoveries are among the most important and controversial to have confronted prehistorians for many decades; they concern the intellectual qualities which, he claims, lie behind the design and positioning of the stone circles and standing stones and are of a kind which, if accepted, must completely alter our picture of Neolithic British society. Thom's work is, however, couched in highly technical and mathematical terms and can be hard going even for those reasonably competent numerically—though the rewards for perseverance are great.

Dr Wood has succeeded admirably in his task. Here is a lucid, carefully composed and balanced account of the findings of the archaeoastronomical school which makes even the most difficult of these ideas reasonably plain. After reading chapter 7 the reviewer found himself for the first time—after eleven years of experience of this field—with a fair grasp of Thom's theory of the use of the fan-shaped stone rows. This is that they were ancillary apparatus at some lunar observatories which could be used to determine the moon's extreme monthly declinations by extrapolation from the actual observations.

Dr Wood has many sensible things to say about the fallacy of equating the modern skills needed to unravel traces of ancient geometry and astronomy with the prehistoric skills involved. As he says, twentieth century man easily forgets how simple and effective the techniques of the pre-scientific age can be and tends to assume that the ancients must have been phenomenally wise to have done with Stone Age equipment what we use theodolites and electronic calculators to do. In its extreme form, this false premise leads

to the belief that all powerful extra-terrestrials must have been involved. And a milder form of this naive belief leads even some archaeologists to maintain that Thom's deductions are simply not credible because Neolithic man could not have possessed the advanced mathematical and astronomical knowledge that he possesses. Of course they did not, but the same results could still have been achieved from a much simpler technological and intellectual base.

Particularly useful is Dr Wood's careful description in chapter 3 of the methods by which the various geometrical shapes Thom believes were incorporated in stone circle designs—true circles, ellipses, flattened circles and egg-shapes—could have been laid out on the ground using only simple equipment like loops of rope, pegs and measuring rods. This exercise provides a further illustration of why one should not attribute too much abstract knowledge to the megalith builders.

There is little doubt that right-angled triangles were the basis of many of these geometrical shapes and it is easy to conclude that the attraction to the circle-builders of the perfect ones found—the 3:4:5, 5:12:13 and 8:15:17 triangles—was the relationship between the squares on their sides thought to have been discovered by Pythagoras in the sixth century BC.

The idea that the Neolithic circle-builders of Britain anticipated Pythagoras by two millennia or more is compelling and would, if true, considerably alter our ideas on the history of intellectual thought. Dr Wood points out, however, that the fact that some not quite perfect triangles were used—such as $8^2 + 9^2 \approx 12^2$ (actually 12.04)—almost certainly means that these numbers were used because they gave 90° angles when laid out on the ground. We certainly cannot assume that the circle-builders also knew the Pythagorean theorem.

Dr Wood brings the same lucidity and common sense to his review of the astronomical qualities claimed to exist in the standing stone sites and gives us, for example, a useful and up-to-date account of the various theories current about how Stonehenge might have been used as an observatory. Anyone wanting a reliable guide through what sometimes seems like a

maze of theory and speculation about this site cannot do better than this.

Prehistorians will not be satisfied with the relatively meagre amount of space given to the more traditional kinds of archaeological evidence and some will feel that their objections to the ideas of the archaeoastronomical school are not adequately covered (though it is true that little of this is actually in print).

Dr Wood is clearly much more at home with the technical and mathematical evidence than with the historical and archaeological. This shows, for example, in his discussion of the concept of the prehistoric unit of length termed the Megalithic Yard; the statistical uncertainties sway him against the idea but the parallel, historical evidence published by the reviewer—which provides striking independent support for the existence of this unit—is not mentioned. However, the book is intended primarily to be a guide through the complexities of archaeoastronomy and archaeogeometry and it succeeds extraordinarily well. □

Euan MacKie is at the Hunterian Museum, University of Glasgow, UK.

Catastrophe theory

Catastrophe Theory and Its Applications Surveys and Reference Works in Mathematics. By T. Poston and I. Stewart. Pp.491. (Pitman: London, 1978.) £25.

HERE at last is the first connected account of catastrophe theory written for people who are not pure mathematicians but who want to understand the applications of this new branch of geometry. Previously there has been only Thom's classic *Structural Stability and Morphogenesis*, often as deeply obscure as it is stimulating, and Zeeman's *Collected Papers 1972-1977*, often brilliantly clear but necessarily disconnected.

The first half of Poston and Stewart's book presents the mathematics of catastrophe theory. They explain clearly Thom's listing of the ways in which critical points of functions (that

is, maxima, minima and saddles) of n variables can coalesce as k parameters vary. The central classification theorem is not proved, but the main ingredients of the proof (transversality, stability, and so on) are very fully described, to the point at which it becomes clear why the catastrophe hierarchy depends strongly on k but hardly at all on n . In applications one often encounters functions that are not in the form of one of Thom's standard polynomials; then intricate rules determine which catastrophe is involved. It is one of the pleasant features of this book that a whole chapter is devoted to these. The interplay between algebraic and geometric ideas is emphasised throughout with the aid of a large number of diagrams. Functions are considered in the modern way, as mappings between sets, and the corresponding notation is used abundantly. However, it is explained at the beginning, and there is sufficient reversion to the old-fashioned " $f(x)$ " for traditionally educated scientists not to lose the thread of the argument.

The second half of the book describes some applications. These are

mostly in the physical sciences, so that it is possible to state definitely what 'potential function' it is whose coalescing critical points give the catastrophes. In Zeeman's pretty theory of ship stability, for example, the potential is gravitational energy; in optical caustics it is the ray transit time (more generally, the action); in beam buckling problems it is elastic energy; in fluid flow it is the stream function; and in phase transitions it is the Helmholtz free energy. Usually the fold and cusp yield little not already known to specialists in these various fields; only with the swallowtail, umbilics and higher catastrophes does one start to generate surprising richness of behaviour and genuine applications to the theory as opposed to mere illustrations.

These authors are masters of advanced exposition, and they are to be congratulated on producing what I am sure will become a classic in its subject. The publishers deserve credit for the high standard of presentation, but not for the price

Michael Berry

Michael Berry is Reader in Physics at the University of Bristol, UK.

Molecular biochemistry

Electrical Interactions in Molecular Biophysics. By R. Gabler, Pp. 352. (Academic: New York, San Francisco and London; 1978.) \$25; £16.25.

This text forms a very readable handbook which outlines the fundamentals of electrostatic and dielectric theory on the one hand and of chemical bonding and molecular biochemistry on the other. From the beginning, the chemistry is given in terms of organic macromolecules. The author stresses the electrostatic nature of molecular interactions and takes care to develop the concepts of dipole moments and dielectric constants.

A good chapter uses these foundations for a detailed account of the various types of charge and dipolar interactions encountered in real molecules together with some idea of their relative importance. Even though the author uses tables to full advantage in attempts to give the reader a feel for the magnitudes of dipole moments, dielectric constants and polarisabilities in real bonds and molecules, the book lacks the ability to convey confidence and insight as to how the reader should treat, evaluate and really understand the complicated behaviour of say the nucleic acids, globular proteins or poly-

saccharides, for example. Three good chapters form condensed, readable but detailed resumés of Van der Waals forces, Debye-Hückel theory and the structure of water. Emphasis for these is again placed on biopolymer materials.

The final chapter on experimental electrical techniques is somewhat dis-

appointing, however, in that it deals almost exclusively with electrophoretic methods. Nevertheless, this particular method is described very well. It is less fortunate that, even though the measurement of dielectric constants and dielectric dispersion data feature strongly in the book, they are tucked away in earlier theory chapters rather than in the experimental chapter. Other novel methods such as ion exchange chromatography, isoelectric focusing and precipitation get but brief mentions, and electro-optic phenomena are by-passed altogether.

In conclusion, the topics with which the book deals are treated well. The book provides a very readable and concise account of the electrical and interaction phenomena encountered in biopolymer solutions and makes a valiant attempt to link the fundamentals of electrostatics and biochemistry. However, it is perhaps a pity that, after all the theoretical and conceptual material, the author did not give examples of how the experimental data could be analysed, interpreted and related to the basic properties and functions of macromolecules. A very good handbook for graduate students and researchers in the field of molecular biochemistry in general and for those engaged in electrical or dielectric measurements in particular.

British bryophytes

The Moss Flora of Britain and Ireland. By A. J. E. Smith. Pp. 706 (Cambridge University Press: Cambridge and London, 1978.) £27.50.

FIFTY-FOUR years have elapsed since the publication of a comprehensive account of British bryophytes. Smith's new book is a worthy replacement for Dixon's *Handbook*, as it combines succinct detail of text with splendid illustrations. It is easier to use than the old *Handbook*, for illustrations are scattered throughout the text rather than being grouped at the end. In many respects it matches the more recent and most popular guide to mosses by E. V. Watson (*British Mosses and Liverworts*; Cambridge University Press second edition, 1968) but surpasses this book in its comprehensive coverage; 692 species are described

and illustrated. It lacks the habit drawings, which were a valuable feature of Watson's book, especially for beginners, but this is not a serious deficiency.

Profuse taxonomic revisions have occurred since Dixon's *Handbook* and the new names will undoubtedly find more widespread acceptance as a result of this publication. *Mnium* now proliferates into *Plagiomnium* and *Rhizomnium*. *Acrocladium* is now *Calliergon* (though we are spared *Calliergonella cuspidata*), and so on. The treatment of that awkward genus *Sphagnum* (contributed by M. O. Hill) is excellent.

This is a book which will be greeted enthusiastically by amateur and professional botanists alike. The price is high but this should not deter the enthusiast; it is worth every penny.

Essays in Microbiology

edited by **J.R. Norris**, *ARC Meat Research Institute and Department of Bacteriology, University of Bristol*
and **M.H. Richmond**, *Department of Bacteriology, University of Bristol*.

This series of essays on general microbiology is written by world authorities and provides a valuable basis for undergraduate study. It contains sixteen essays on a range of topics and will be a useful addition to the library of any Microbiology Department where it will serve as an introduction to the whole subject.

Contents: What is Microbiology?; Form and Function: I Bacteria; Form and Function: II Fungi; Form and Function: III Viruses; Form and Function: IV Protozoa; The Chemistry and Composition of Microorganisms; Dynamics of Microbial Growth; Intermediary Metabolism; Classification of Microorganisms; The Genetic Organisation of Bacteria and its Expression; Interactions between Phage and Bacteria; The Determinants of Microbial Pathogenicity; Resistant Forms; Symbiosis in the Microbial World; Bacterial Nutrition.

July 1978 538 pages

Water Pollution Microbiology Vol. 2

edited by **R. Mitchell**, *Harvard University*.

Provides up-to-date microbiological based information on causes and control of water pollution. Leading microbiologists and environmental engineers evaluate new concepts and techniques and demonstrate the synthesis between microbial ecology and environmental engineering for water pollution control. They examine the role of microorganisms as causative agents of ecological and public health hazards in natural waters, as indicators of water pollution, and as purifying agents.

Life Science Physics

by **J.W. Kane** and **M.M. Sternheim**,
both of the University of Massachusetts.

The overall unity of science is demonstrated here by relating physics to biomedical disciplines and systematically using life science topics to illustrate physical principles. Contains examples from biological systems and applies physics concepts to them in detail. Topics no longer of great interest to physicists, but relevant to the life sciences, such as geometric optics, the mechanics of fluids and acoustics are discussed.

August 1978 684 pages

Potato research

The Potato Crop: The Scientific Basis for Improvement. Edited by P. M. Harris Pp. 730 (Chapman and Hall, London; 1978.) £25

THIS book is one of the first of a series of crop monographs; those on barley and potatoes have appeared and one on wheat is promised. According to the general editor of the series, E H Roberts, the aim is to provide authoritative and comprehensive summaries of current scientific knowledge aimed at teachers, students and research and advisory workers (they are not meant as practical manuals for farmers). The project as a whole is timely because the past 20 years has seen a formidable growth of knowledge of the scientific aspects of all our crops, yet there are few good recent monographs of temperate crops available, tropical crops, perhaps surprisingly, have been, on the whole, rather better served.

To what extent, then, does the present work fulfil these intentions? In general, I think it does so very

well. The book, a large one, is composed of 17 chapters which start with history and biosystematics, and go on through morphology, growth physiology, mineral nutrition, water relations, plant density and 'seed' management to mechanisation and weed control; there follow treatments of diseases, pests, tuber quality, storage, breeding, and economics, and the book concludes with a somewhat more speculative (and very interesting) chapter on the application of physiological ideas to the enhancement of crop performance.

The editor has done a good job of making a reasonably coherent whole out of diverse material contributed by 21 authors. The book is well made, the illustrations and index are adequate, and bibliographies (chapter-by-chapter) seem to be fairly complete, misprints and errors are few. Individually, the writers clearly know their subjects well, so the work as a whole is authoritative as well as comprehensive. The facts that our knowledge has improved greatly in recent decades and that the management of the crop and the product is shifting rather rapidly as new technology emerges become very apparent on reading this book. That knowledge and management are both yet imperfect, however, is also clear

and several authors draw attention to deficiencies in these respects.

This book will surely become the standard reference work for the crop and anyone seriously concerned with potato research will need to have it near to hand. Teachers will find it useful and so, perhaps, will some potato farmers (who tend to be knowledgeable enthusiasts); but it is not a practical manual.

There are two defects which should be considered in preparing a revision. First, few readers will find 30 odd pages of taxonomy of wild species very useful in the crop physiological context of this book, and the first two chapters could therefore be condensed into one without loss of content but with some saving of space. Second, though the bibliographies are reasonably international in character, the more agricultural parts of the text are much coloured by Western European, especially UK, practice. A wider viewpoint (including the place and potential of the crop at low latitudes) would be desirable.

N. W. Simmonds

N. W. Simmonds is Lecturer in the School of Agriculture at the University of Edinburgh, UK.

Quantum electrodynamics textbook

Quantum Electrodynamics. By S. N. Gupta. Pp. 226 (Gordon and Breach, New York, Paris and London, 1978.) £25 30.

QUANTUM electrodynamics is the relativistic quantum theory of photons interacting with electrons and other charged leptons. It grew between about 1930 and 1950, as the natural result of combining special relativity with quantum theory. It has made some spectacularly accurate predictions, and it is one of the triumphs of mid-twentieth century physics.

There are few textbooks on just this subject, and the appearance of a new one is noteworthy, particularly when it is by someone like Professor Gupta, who has been a frequent and important contributor to the subject.

One of the best things about this book is its conciseness. Everything is done as economically and elegantly as possible, with no superfluous words. To achieve this compression some things inevitably have had to be sacrificed. I missed any discussion of polarisation,

of bound states, and, most seriously, of the experimental confirmation of the subject. There is a paucity of references, and there are none at all to other textbooks.

On technical matters, the gauge condition is dealt with using the indefinite metric, and regularisation is treated in terms of auxiliary fields. Scattering theory is treated rather perfunctorily. The difficult subject of renormalisation is briefly but, to my taste, sensibly and adequately covered.

Quantum electrodynamics is not a self-contained subject. In calculating the magnetic moment of the electron, for example, weak interactions and the virtual production of strongly interacting particles would have to be included if sufficient accuracy were required. Professor Gupta's book may be one of the last to confine itself to electrodynamics. It is none the worse for that; but a discussion would have been welcome of the place of quantum electrodynamics within modern physics.

This brief and clear book would be a good one from which to learn the subject. It is a pity that the price is too high for most students to pay.

obituary

R. G. W. Norrish, 1897-1978

THE death of Professor Ronald George Wreyford Norrish in his 81st year at Cambridge on 7 June 1978 marks the passing of an era notable for remarkable developments in chemistry, among which must be included the advance to maturity of reaction kinetics as a discipline in physical chemistry. Throughout Norrish's research career, extending over more than forty years, he was intimately concerned with a wide variety of subjects, including photochemistry, atomic and free-radical reactions, chain processes such as ignition and combustion and polymerisation, and energy transfer between and within molecules. In all these his studies led to important, and sometimes revolutionary, advances. Wide as his research activities were, yet they were intertwined, with the thread of an intense interest in the behaviour of activated species and the study of the latter by kinetic techniques, running through them.

Norrish's first photochemical work, carried out in 1923 in collaboration with E. K. Rideal, was a study of the photochemistry of aqueous potassium permanganate solutions. At that time photochemistry was in its infancy. The first application of quantum theory to photochemistry had been made by Einstein in 1912 in the form of his law of photochemical equivalence (although in some respects this was anticipated by work of Stark) and its precise applicability to photochemical reactions was still a matter for debate. The remarkable paper by Franck on the elementary processes of photochemical reactions did not appear until 1925. Norrish published a number of interesting papers before 1930, notably those on the photochemistry of nitrogen dioxide, in which he demonstrated a photochemical threshold and the achievement of a photostationary state.

In the period up to the middle 1930s correlation between photodecomposition and photophysical phenomena, such as spectral character and the appearance of fluorescence, engaged the attention of photochemists and Norrish's laboratory in Cambridge occupied a prominent position in these studies. Of his photochemical work before World War II, his long series of investigations of the photolysis of carbonyl compounds is perhaps particu-

larly far-reaching.

The first paper, in 1928, concerned with the photodecomposition of glyoxal, was followed by reports of studies of formaldehyde, acetaldehyde, acetone and a variety of aldehydes and ketones carrying longer hydrocarbon chains. These led to the recognition of the now famous Norrish Type I and Norrish Type II reactions, illustrated by the equations

in which the groups R^1 and R^2 are understood to contain one or two carbon atoms. The observation that Types I and II reactions are influenced strongly by the physical environment—i.e. whether gas phase or condensed phase—provided a most important 'spin-off', namely the first experimental illustration of the Franck-Rabinowitch cage mechanism operative in solution.

Norrish's interest in intense light sources for photolysis seems to have arisen during World War II. I recall a comment (suitably embellished), made near the end of the war, that he intended to get a searchlight to photolyse keten and to trap the resulting methylene by the Paneth method. At that time, rudimentary ideas of flash photolysis may have been growing in his mind.

Flash photolysis, pioneered by Norrish and Porter and their coworkers, was a truly revolutionary development. It makes use of a powerful short-lived 'photoflash' which brings about rapid dissociation of the absorbing species into radicals or atoms. A second weaker spectroscopic flash ('specflash') triggered electronically at a precise interval after the first, permits the observation of transient species and by varying the time between the two flashes the kinetics of the formation and decay of such species may be studied. A fascinating account of these developments, extending from pyrolysis and combustion processes to vibrational relaxation phenomena, was given by Norrish in his Faraday Lecture to the Chemical Society. The immense impact of this technique on the study of fast reactions and the behaviour of active species is now too well-known to require description and the award of the

Nobel Prize for Chemistry in 1967 jointly to Norrish and Porter and to Eigen was universally welcomed.

Norrish's interest in chain processes was evident from his early work on the hydrogen-chlorine reaction in which he elucidated the inhibitory effects of oxygen and ammonia. Adoption of a new technique (continuous photometric analysis) enabled Norrish and Ritchie to establish that the retarding effect of HCl in pure systems and systems containing oxygen is attributable to the process

Norrish's work on the kinetics of this chain reaction, many features of which had defied solution by earlier workers, established his eminent position among kineticists.

Much of Norrish's work on combustion was centred on the transition between slow reaction and ignition and particularly the dependence of the ignition boundaries on the concentrations of various additives (e.g. NO_2 , NOCl , CCl_3NO_2). During the early stages, Semenov was developing his classical theories of thermal and isothermal ignition; Norrish saw the necessity for combining both these in a branched-chain thermal theory. Although some of the detailed interpretations have been modified as the result of applications of new experimental techniques, there is no doubt that the beautiful work of Norrish and his colleagues, made over a long period, has provided much of the basis of our present understanding of these complex processes. The experimental demonstration of degenerate (or delayed) branching in hydrocarbon combustion was an outstanding contribution.

Schizophrenia: Towards a New Synthesis

edited by J. K. Wing

October/November 1978, xii + 292pp., £8.00/\$16.50 0.12.759450.7

Advances in the understanding of schizophrenia have lately been made in the teeth of controversy and confusion, part of which is due to differences in terminology or diagnostic criteria, and part to the elusive nature of the condition itself. It seems clear that the truth about schizophrenia is not to be found within one restricted field of knowledge. At last, however, the beginnings of a convincing synthesis are appearing, balancing biochemical and genetic evidence with findings from clinical psychiatry and the behavioural sciences, establishing a basic set of symptoms and disposing once and for all of the argument that schizophrenia is a myth. This book provides a comprehensive and readable account of modern knowledge about schizophrenia.

Chemisorption of Gases on Metals

F. C. Tompkins

October/November 1978, x + 372pp., £16.80/\$34.75 0.12.894650.7

This volume will fill the gap in providing an up-to-date account of chemisorption on metals for the graduate and postgraduate student and specialist, in forming a basis for further studies. The early part of the book introduces the thermodynamics and statistical mechanics of chemisorption; but subsequent chapters on the kinetics of absorption and desorption processes place their emphasis on recent investigations of sticking probabilities, precursor and multiplet states, energy accommodation and molecular beam scattering. Later chapters are concerned with the geometric and electronic properties of surfaces and their overlayers, and include adsorption-reflection infra-red spectrometry, LEED, Auger, ultra-violet and X-ray photoelectron spectroscopy, ion neutralization and energy loss spectroscopy, elastic resonance and inelastic tunnelling in field emission. A brief account of the status of modern theoretical studies is also included.

Digital Filters and Their Applications

V. Cappellini, A. G. Constantinides and P. Emilian

October/November 1978, xvi + 384pp., £20.50/\$42.40 0.12.159250.2

Over the last decade, there have been remarkable developments in sampled data processing methods and techniques, the most important of which is digital filtering. These developments have resulted in many new and useful applications for digital filters in areas such as communications, radar-sonar, experimental physics, aerospace systems, biomedicine and remote sensing. This book presents a synthesis of the theory and design of digital filters (1-D and 2-D) together with a description of their practical utilization in the most important areas of signal and image processing. The book is divided into three main parts. The first, tutorial in character, summarizes the basic relationships for the different types of digital filter, and presents design methods. The second tackles practical problems of design and implementation, and the third describes the impact of digital filters in research, operative and industrial areas.

Active and Passive Thin Film Devices

edited by T. J. Courts

October/November 1978, xxiv + 858pp., £60.00/\$124.25 0.12.193850.8

In recent years both the technology and the basic understanding of thin film phenomena have advanced rapidly. Although few new passive thin film devices have been developed, the materials used have become increasingly well understood, with better knowledge of their properties, and at the same time developments have been made in the theories of charge transfer. The rate of development of active devices, however, is very rapid and it seems certain that in the very near future these will have a major impact on many fields including information display, communications, energy conversion and detection, medicine, computing and instrumentation. There is therefore a great need for a book such as this which provides a comprehensive account of the properties of thin films, the theories of thin film phenomena and their wide range of applications.

Development in Mammals

Development in Mammals is an advanced, critical and informative work of reference which serves not only to record the current states of knowledge and controversies in the field of mammalian development but also point the direction of new approaches. Authors contributing to this series have been encouraged to extend their observations beyond the narrow range of mammalian development wherever interdisciplinary approaches or parallels drawn with other areas might appear useful.

edited by MARTIN H. JOHNSON

Volume 3

1978. viii + 472 pages. US \$ 61.00/
Dfl. 140.00. ISBN 0-7204-0663-3

Volume 3 of *Development in Mammals* shows some alterations in style, but has adopted the same approach to content as did volumes one and two. Authors have again been encouraged to develop new ideas and to be provocative, and to use unpublished data where these would support an argument. Within this flexible framework, a number of contributions have been received relating to four broad categories of topic.

Two of the contributions deal with the acrosome reaction, one approach biochemical and the other biophysical. Two contributions are concerned specifically with models for cell:cell interaction in development, either by viral particles or through localised fluidity changes in cell membranes. Five contributions deal with the relationships between stem cells, pluripotentiality and the transmission of the germ line. Finally, three contributions are concerned with the fundamental aspects of morphogenesis - proliferation, migration and clonal growth.

Volume 2

...this volume is good value and augurs well for the next of the series."

In the field of polymerisation, Norrish also made pioneering kinetic studies. The best-known is probably that concerned with the acceleration which occurs in the later stages of free-radical polymerisation, to which the name 'gel-effect' has now been attached. Norrish and Smith showed that this is the result of a steadily decreasing rate of chain termination which sets in when the viscosity becomes high. A nice example of the cross-fertilisation of his ideas is provided by his work on the photolysis of poly(methylvinylketone), which was found to undergo photolysis in solution according to both Types I and II. The former yields macroradicals which, in the presence of a polymerisable monomer, give block copolymers.

Norrish had intense energy and enthusiasm and an all-consuming desire to get to the bottom of things by experimental means. These qualities could be disconcerting to his research students, who were sometimes expected to obtain definitive results between 9.30 a.m. and 6.0 p.m. on the same day (bank-holidays included!). Norrish was a generous and warm-hearted, yet forthright, person. His membership of the Savage Club reflected his enjoyment of meeting people, especially those distinguished in professions remote from his own. He had a tremendous zest for life and his hospitality became legendary, not only on the more formal occasions, but also in his entertainment of friends and colleagues from all parts of the world at his home in Park Terrace. There, one might be regaled with recordings of Japanese music or a lecture by Rutherford, or enter into quasi-philosophical discussions of the 'fourth law' of thermodynamics and when Norrish received his honorary degree in the University of Liverpool, the Public Orator recalled the remarkable aptness of Praed's words

'Beginning with the laws which keep
The planets in their radiant courses,
And ending with some precept deep
For dressing cels, or shoeing horses.'
It might truly be said that with Norrish every evening was Christmas eve.

Things Cantabrigian occupied a very special place in Norrish's affections. He was born and educated in Cambridge and effectively spent all his working life there. In 1937, after the death of T. M. Lowry, he had become the second holder of the Chair of Physical Chemistry and subsequently the head of the separate Department of Physical Chemistry. He was justifiably proud of the department he had built up and had strong associations with his College (Emmanuel) of which he was Senior Fellow at the time of his death. His lectures on physical chemistry were

often vividly illustrated by spectacular demonstrations of his favourite phenomena in photochemistry and chain processes. During the war, his department was largely concerned with problems related to the war-effort, such as suppression of gun flash and the development of incendiary materials; during this time Norrish was Chairman of the Incendiary Projectiles Committee.

Norrish's distinction naturally led to his receiving many honours. He was elected Fellow of the Royal Society in 1937 and received honorary doctorates from the Sorbonne, and the Universities of Lancaster, Leeds, Liverpool, Sheffield and British Columbia. He was awarded the Meldola Medal of the Institute of Chemistry (1928), the Davy Medal of the Royal Society and the Liversidge Medal of the Chemical Society (1958), the Lewis Gold Medal of the Combustion Institute (1964), the Faraday and Longstaff Medals of the Chemical Society (1964, 1968) and was a member of eight foreign Academies of Science. During 1953-55 he was President of the Faraday Society, and in 1961 was President of Section B of the British Association for the Advancement of Science. In 1966 he gave the Bakerian Lecture of the Royal Society. Notwithstanding all his honours, he retained an innate modesty which allowed him to accord to others, particularly his junior colleagues, due appreciation of their efforts.

In 1926 he married Anne, the eldest daughter of A. E. Smith, of Manchester, who survives him. They had twin daughters.

C. H. Bamford

J. P. Kendall

PROFESSOR JAMES PICKERING KENDALL, F.R.S., F.R.S.E., Emeritus Professor of Chemistry, University of Edinburgh, died in Edinburgh on 14 June 1978.

He was born on 30 July 1889 in Chobham, Surrey, and was educated at Farnham Grammar School and Edinburgh University. A distinguished undergraduate career was followed by work on exact conductivity measurements, first in Edinburgh and later with Svante Arrhenius at the Nobel Institute, Stockholm. Kendall was inspired by Arrhenius, but found research facilities in the Institute disappointing and after a spell he went to the better equipped Technological Institute of St. Petersburg.

In 1913 Kendall went to Columbia University, New York, as an instructor in chemistry and in 1922 was promoted to a full professorship. He carried out research on a variety of topics includ-

ing the formation of addition compounds in solution and ionisation equilibria. A good example of his inclusive and discriminating approach to research is contained in a long, critical and polemical paper on the properties of strong electrolytes in solution in which facts and arguments are marshalled against the views and postulates of Ghosh.

Probably his most important work was the attempt to separate isotopes and mixtures of rare earths, a pioneer effort at a period when the sophisticated armoury of the modern chemist was not available. Isotopic separation eluded him, but by the ionic migration method he effected a substantially complete separation of yttrium from erbium. At the same time he undertook the revision of Alexander Smith's famous series of chemistry textbooks, a task which made increasing demands on his time and energy.

In 1927 Kendall was elected a Fellow of the Royal Society and a year later succeeded Sir James Walker as Professor of Chemistry in the University of Edinburgh, a post he held until his retirement in 1958. He immediately made full use of his administrative ability and business acumen into extending the research facilities of his department, and with the help of men like J. A. V. Butler, E. B. Ludlam, M. Ritchie and H. W. Melville, succeeded in building up a thriving school of physical chemistry. Apart from unsuccessful attempts to separate the hydrogen isotopes in water and to detect the calcium isotope with mass 41 in the potassium-rich deposits of Rhiconich in Sutherlandshire Kendall gave up research and concentrated on writing books. These included *At Home among the Atoms* and *Young Chemists and Great Discoveries* and the lively and readable biographies of Michael Faraday and Humphry Davy. In 1938 he wrote *Breathe Freely* in which he correctly predicted that in the event of war poison gas would not be used.

Kendall was an excellent lecturer and he gave the 1938/39 course of Christmas lectures at the Royal Institution, in London. In one of the lectures he performed the famous boiling lead experiment, when his daughter Jean passed her hand through the stream of white hot metal. He also took a great interest in the Royal Society of Edinburgh and served first as General Secretary (1936-1946) and then as President (1949-1954). In his younger days he enjoyed bicycling and he was a very good bridge player. He was twice married and his second wife, Jean, tended him devotedly in his latter years of ill-health. He leaves a son and two daughters.

Oxford Books for Students

Physical Chemistry

P. W. Atkins

'What convinces me that this is a book that should be widely adopted, and which will be sought after by undergraduates whatever their teachers may recommend, is that the whole work is distinguished by penetrating insight allied to consistent and exceptional clarity of expression.' *The Times Higher Education Supplement*. £15 paper covers £7.95

Primary Metabolism

A Mechanistic Approach

J. Staunton

The traditional line of demarcation between biochemistry and chemistry has dissolved in recent years as chemists and biochemists have joined forces in investigating the mechanisms of reactions which take place in living systems. This book introduces this area of common interest to students of both chemistry and biochemistry. £6.50 *Oxford Chemistry Series*

Secondary Metabolism

J. Mann

This book is concerned with the biosynthesis, biological activity, and ecological significance of secondary metabolites (natural products). All the major classes of secondary metabolites are considered systematically, according to the basic 'building blocks' from which they are derived. Examples are given of compounds found in insects, plants, and micro-organisms; and the pharmacological and toxicological properties are emphasized where relevant. £9.75 *Oxford Chemistry Series*

Mathematical Cosmology

Peter T. Landsberg and David A. Evans

This book gives readers a quantitative understanding of some important aspects of general relativistic cosmology, starting only with school mathematics and Newtonian ideas in physics. It is concerned mainly with various models that have been proposed to explain the large-scale structure of the universe: the Friedmann models, steady-state models, and model universes involving pressure. £6.95

The Bowels of the Earth

John Elder

This paperback reprint has replaced the boards edition which was published in 1976. 'Original, persuasive, intensely individual . . . the book is plainly a *tour de force*, and it may set a new model for scientific exposition . . . The prose . . . is direct and evocative.' *Scientific American*. Paper covers £2.95

Human Growth and Development

Wolfson College Lectures 1976

Edited by Jerome S. Bruner and Alison Garton

These papers explore some of the biological, social, and political factors involved in growing up in modern society. They indicate the strong admixture of biological and social determinants that influence behaviour during child development, and two main themes run through the book: the importance of achieving social connection, and the active nature of childhood. £4.25 paper covers £2.25

Mechanics and Motion

L. Mackinnon

This book, based on the first-year course given by the author at the University of Essex, provides a survey of those topics that are an essential background to modern physics and advanced engineering. Throughout, the emphasis is on the basic physical concepts necessary to a study of the more advanced courses that will follow. £6 paper covers £3.25 *Oxford Physics Series*

The Properties of Nuclei

G. A. Jones

This book describes the properties of nuclear levels, starting with stable states and progressing, via quasi-stable states (radio-active ground states and nuclear stable excited states), to unstable (nucleon-emitting) states. The shell model, the collective models, and the optical model of the nucleus are described, and nuclear reactions are introduced in terms of the compound nucleus and direct processes. £5.95 *Oxford Physics Series*

1978 **Oxford University Press**

Learning Strategies

Edited by HAROLD F. O'NEIL, JR.

A Volume in the EDUCATIONAL TECHNOLOGY Series

CONTENTS: D. Dansereau, The Development of a Learning Strategies Curriculum. C. Weinstein, Elaboration Skills as a Learning Strategy. F. Richardson, Behavior Modification and Learning Strategies. R. N. Singer, Motor Skills and Learning Strategies. J. S. Brown et al., Artificial Intelligence and Learning

Strategies. R. S. Logan, An Instructional Systems Development Approach for Learning Strategies. J. W. Rigney, Learning Strategies: A Theoretical Perspective. H. Wagner and R. J. Seidel, Program Evaluation.

1978, 256 pp., \$15.00/£9.75 ISBN: 0-12-526650-2

Group Processes

Papers from *Advances in Experimental Social Psychology*

Edited by LEONARD BERKOWITZ

CONTENTS: J. R. Hackman and C. G. Morris, Group Tasks, Group Interaction Process, and Group Performance Effectiveness: A Review and Proposed Integration. J. R. Hackman and C. G. Morris, Group Process and Group Effectiveness: A Reappraisal. L. R. Hoffman, Group Problem Solving. L. R. Hoffman, The Group Problem-Solving Process. E. P. Hollander and J. W. Julian, Studies in Leader Legitimacy, Influence, and Innovation. E. P. Hollander and J. W. Julian, A Further Look at Leader Legitimacy, Influence, and Innovation. F. E. Fiedler, A Contin-

gency Model of Leadership Effectiveness. F. E. Fiedler, Recent Developments in Research on the Contingency Model. K. L. Dion et al., Why Do Groups Make Riskier Decisions Than Individuals? N. Miller, A Questionnaire in Search of a Theory. M. E. Shaw, Communication Networks. M. E. Shaw, Communication Networks Fourteen Years Later. N. E. Waxler and E. G. Mishler, Experimental Studies of Families.

1978, 448 pp., \$13.50/£8.75 ISBN: 0-12-091840-4

Current Topics in Membranes and Transport VOLUME 11

Cell Surface Glycoproteins: Structure, Biosynthesis, and Biological Function

Edited by FELIX BRONNER and ARNOST KLEINZELLER

CONTENTS: A. Rothstein, The Cell Membrane—A Short Historical Perspective. J. Sturgess et al., The Structure and Biosynthesis of Membrane Glycoproteins. R. L. Juliano, Techniques for the Analysis of Membrane Glycoproteins. J. R. Riordan and G. G. Forstner, Glycoprotein Membrane Enzymes. R. W. Compans and M. C. Kemp, Membrane Glycoproteins of Enveloped Viruses. M. J. A. Tanner, Eryth-

rocyte Glycoproteins. L. A. Culp, Biochemical Determinants of Cell Adhesion. K. D. Noonan, Proteolytic Modification of Cell Surface Macromolecules Mode of Action in Stimulating Cell Growth. M. Letarte, Glycoprotein Antigens of Murine Lymphocytes.

1978, 544 pp., \$39.50/£25.65 ISBN: 0-12-153311-5

The Unity of the Senses

By LAWRENCE E. MARKS

A Volume in the COGNITION AND PERCEPTION Series

The Unity of the Senses demonstrates that the senses of sight, hearing, taste, smell, touch, and temperature are closely knit systems that bear many important resemblances rather than being separate, independent channels. The first part (Chapters 1-6) deals with sensory and perceptual phenomena, and explores in depth four central topics: the common

perceptual function of the senses; similarities in sensory experiences; common psychophysical properties; and common neural properties. In the second part (Chapters 7-8), the author examines how the unity of the senses reveals itself in language, especially in poetic language.

1978, 304 pp., \$17.50/£11.35 ISBN: 0-12-472960-6

Social Insects VOLUME 1

Edited by HENRY R. HERMANN

CONTENTS: H. R. Hermann, Insect Sociality—An Introduction. C. K. Starr, Origin of Insect Sociality. A Review of Contemporary Theory. F. M. Carpenter and H. R. Hermann, Antiquity of Sociality in Insects. C. B. Urbani, Territoriality in Social Insects. M. V. Brian, Caste Differentiation and Division of Labor.

R. H. Crozier, Genetics of Sociality. G. C. Wheeler and J. Wheeler, Larvae of the Social Hymenoptera. D. H. Kistner, Social and Evolutionary Significance of Social Insect Symbionts.

1978, about 450 pp., in preparation ISBN: 0-12-342201-9

Oceanography: CONCEPTS AND HISTORY

Edited by MARAGARET B. DEACON

Volume 35 of Benchmark Papers in Geology

SECTION HEADINGS: Some Seventeenth Century Instructions For Making Scientific Observations At Sea. Circulation of the Ocean. Tides Waves. Chemistry of Sea Water. Depths of the Ocean and the Sea Bed. Marine Biology.

1978, 416 pp., \$25.00/£16.25 ISBN 0-12-786340-0

Published by Dowden, Hutchinson and Ross, Inc.

UNIVERSITY COLLEGE LONDON DEPARTMENT OF ANATOMY AND EMBRYOLOGY TECHNICIAN GRADE 6

required to be in charge of a Neurochemistry laboratory for an active research group. Biochemical/Pharmacological background with sound knowledge of assay techniques essential. Particular experience with adenine nucleotides, catecholamines, polypeptides and prostaglandins would be an advantage. This post is Grant-supported until May 1982 when renewal will be applied for.

Salary in range £4,119 to £4,830 inclusive of London Weighting.

Application forms from Personnel Officer (Technical Staff FB36), University College London, Gower St., London WC1E 6BT. 7062(A)

UNIVERSITY OF OXFORD

Applications are invited for the post of Medical Laboratory Scientific Officer to work on the synthesis of haemoglobin in normal human development and in various inherited diseases.

Applicants should hold a degree in Biochemistry (or related subjects) or B.Sc. in Medical Laboratory Science; previous laboratory experience would be preferred.

The post is funded for four years by a grant from the M.R.C. Salary range £3,261 to £4,680 per annum.

Further details and application form may be obtained from the Administrator, Nuffield Department of Clinical Medicine, Radcliffe Infirmary, Oxford OX2 6HE. Closing date for applications September 21, 1978 7023(A)

THE GRASSLAND RESEARCH INSTITUTE Hurley, Maidenhead, Berkshire HIGHER SCIENTIFIC OFFICER SENIOR SCIENTIFIC OFFICER

A SOIL CHEMIST is required in the Soils and Plant Nutrition Department for studies on the major nutrients in grassland soils.

The main responsibility of the appointee will be to develop methods for evaluating available forms of nutrients and their effects on soils and plants (initially the work will centre on nitrogen).

Minimum qualifications: First or Upper Second Class Honours degree in Chemistry or Soil Science and at least two years' relevant postgraduate experience.

The appointment will be made in the grades Higher Scientific Officer or Senior Scientific Officer.

At least four years' relevant postgraduate experience in Soil Science or other related subject is required for appointment as Senior Scientific Officer.

Evidence will be required of the candidate's ability to carry out research at either level, preferably by reference to published papers.

Salary according to qualifications and experience:

Higher Scientific Officer £4,101 to £4,448.

Senior Scientific Officer £5,154 to £5,898.

There is a non-contributory superannuation scheme.

Applications to the Secretary giving curriculum vitae and the names of three referees quoting Ref 1/C/4 by September 30, 1978. 7053(A)

HARVARD SUMMER SCHOOL POSITIONS IN BIOLOGY

Applications are invited for Summer School teaching positions in Biology. Introductory courses are emphasized with possibility of intermediate offerings. Possible courses include: general biology, zoology, botany, cell biology, physiology, and genetics. Compensation at Harvard median. Applications including C.V. should be sent to:

Dr Marshall R. Pihl
Associate Director
Harvard Summer School
20 Garden Street
Cambridge, Mass. 02138

DEADLINE October 31, 1978.

Harvard University is an Equal Opportunity/Affirmative Action Employer. 7038(A)

THE UNIVERSITY COLLEGE OF WALES ABERYSTWYTH DEPARTMENT OF AGRICULTURAL BOTANY

Applications are invited for the post of RESEARCH ASSISTANT, to work on the Cytology of Festuca species. Fixed-term appointment, up to three years from October 1, 1978 or as soon as possible thereafter. Applicants should have a good honours degree in Genetics, Botany, Agricultural Botany or Biology.

Salary £3,189 per annum on 1B range.

Application forms available from the Registrar, Old College, Aberystwyth, Dyfed. Closing date: September 20, 1978. 7039(A)

UNIVERSITY OF LONDON INSTITUTE OF NEUROLOGY Applications are invited for the post of CLINICAL LECTURER

in Chemical Pathology in the combined departments of Chemical Pathology/Neurochemistry.

The post is recognized by the Royal College of Pathologists as suitable for higher training leading to M.R.C.Path.

In addition there are exceptional facilities for research into various fields of Brain Biochemistry and candidates will be encouraged to undertake work leading to an M.D. or Ph.D.

Enquiries and applications to the Secretary, Institute of Neurology, National Hospital, Queen Square, London WC1 by September 29, 1978. 6063(A)

Coal Survey Specialists

£7000—£8825 based Yorkshire

The National Coal Board have opportunities for 2 Coal Quality Scientists to work as part of a National Exploration team based in Yorkshire which has the task of establishing the long term coal reserves of the nation.

The main work will involve the synthesis of data from boreholes as exploration proceeds; the identification of those quality parameters to which the profitability of any coal mining venture would be most sensitive; and the evaluation of each prospect within both its Regional and National exploration setting. The successful applicants will also participate in appraising the coal quality and utilisation aspects of the Board's major capital investments programme for the development of new capacity.

Applicants should hold an honours degree in either chemistry, geochemistry, fuel technology or a related subject. Experience in one or more of the following fields would be an advantage: fuel technology, coal analysis and utilisation, coal preparation, geological data analysis.

A period of supervision and training will be given where appropriate.

These are permanent positions within Headquarters Geological Branch with an inclusive salary range of £7000—£8825. Attractive conditions of employment.

Please apply with full details to:

NCB

SENIOR MEDICAL OFFICERS

To advise on Chemical Contamination of food and environmental pollution
£12,730

The Department of Health and Social Security is increasingly active over a wide range of important and often controversial "wider health" issues. One expanding area of concern is the level and effects of chemicals in the environment. Particular attention is paid to food toxicity, cosmetics, toxicity of industrial chemicals, and the scientific aspects of smoking.

There are now a number of posts in this expanding area for Senior Medical Officers to advise government on the medical implications involved and to assess data for consideration by expert advisory committees. The work involves consultation with a range of interested parties, including doctors and scientists working in the industrial and

academic worlds. There may also be opportunities to represent the Department in international discussions.

Candidates must be fully registered as medical practitioners in the UK and preferably have experience in such areas as toxicology, biochemistry, pathology and physiology. The salary for these London posts is £12,730, and there is a non-contributory pension scheme.

For further details and an application form (to be returned by September 29 1978) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote ref: S/9896/4. 6081 (A)

THE HOSPITAL FOR SICK CHILDREN GREAT ORMOND STREET LONDON WC1N 3BR

A TWO-YEAR APPOINTMENT

Two-year appointment for the study of GLC methods for urinary catecholamine metabolites. In connection with the diagnosis and treatment of tumours in children. Whitley Council conditions up to 3rd point on MISO scale.

Enquiries to Dr Seakins 01-242 9789 Ext: 13.

Application forms from Personnel Department
01-405 9200 Ext: 228 7005(A)

HARPER ADAMS AGRICULTURAL COLLEGE NEWPORT, SALOP

LECTURER GRADE 2 AGRICULTURAL BOTANIST

Lecturer Grade 2 to be appointed by January 1, 1979, to be responsible for the teaching of Agricultural Botany to a range of H.N.D. and Post Diploma Courses.

Candidates should have an honours degree in Agricultural Botany or similar qualification.

Salary in Burnham F.R. Scale £4,101 to £6,658, point of entry dependent on qualifications and experience.

Further details and application form from The Bursar, Harper Adams Agricultural College, Newport, Salop, TF10 2NB. 7058(A)

MEDICAL SCHOOL HANNOVER Federal Republic of Germany RESEARCH BIOCHEMISTS and RESEARCH ASSISTANTS IN THE DEPARTMENT OF GASTROENTEROLOGY AND HEPATOLOGY

We invite applications from biochemists or chemists who are interested in joining a young and active research group investigating methods of extracorporeal detoxification. Our particular interest is the development of an artificial liver support system using immobilised enzymes isolated from bovine tissue. Biochemical and toxicological aspects of acute liver failure in general constitute the focal point of our research activities.

At least two positions are available for doctoral students with a good honours degree in a relevant subject, and two further positions for fully qualified (Ph.D.) biochemists. Previous experience in this field is not required; we place more emphasis on the individual qualities of the candidates. There is ample scope in the research group for scientists with initiative, and the development of individual ideas is encouraged. A knowledge of the German language is useful but not essential. We offer good salaries, and excellent laboratory facilities.

A curriculum vitae, details of qualifications and experience, the names of three referees, and a passport-sized photograph should accompany the letter of application, which should be sent as soon as possible. The posts can be taken up immediately, or in the next few months by arrangement. Short-listed candidates will be invited here for interview at our cost.

Requests for further details of the posts, and applications should be addressed to: Dr G. Brunner, Medizinische Hochschule Hannover, Oststadt/Innenhaus, Podbielskistr. 380, D3000 Hannover, Federal Republic of Germany 7018(A)

ROYAL MARSDEN HOSPITAL Fulham Road, London SW SCIENTIFIC OFFICER— IMMUNOLOGY

£3,615 to £5,034

Applications are invited from experienced scientific officers for a post which is available immediately. Duties include screening and identifying HLA antibodies, typing of patients and potential donors for the bone marrow transplantation programme, participation in regional and international workshop exchanges of anti and information. New developments include the identification of B antibodies and the application of studies in malignant diseases.

Application Forms from Person Dept. Tel. 352 8171 Ext. 447. Clo date: September 17, 1978. 6078(A)

LABORATORY SCIENTIFIC OFFICER required to work in Department of Histopathology. Anatomy for three years to assist work on the immunology of multiple sclerosis and cell surface antigens of the nervous system. Experience of cells/tissue culture an advantage. Salary for qualified Laboratory Scientific Officer not less than £3,261 £354 London Weighting. Apply writing, stating age and giving details of qualifications and experience quoting the names of two referees to the Secretary, Guy's Hospital Medical School, London SE1 9RT. Additional information obtainable from Leibowitz, Department of Histopathology (Tel. 01-407 7600, ext. 33 6077(A)

UNIVERSITY OF ABERDEEN DEPARTMENT OF NATURAL PHILOSOPHY SENIOR LECTURESHIP

Applications are invited for Senior Lectureship in the Department of Natural Philosophy from candidates well qualified for research and university teaching in theoretical physics. The successful applicant is expected to take up his or her duties as soon as convenient and later than October 1, 1979.

Salary on scale £7,074 to £8,000 per annum, with appropriate place. Further particulars from Secretary, The University, Aberdeen with whom applications (2 copies) should be lodged by October 1, 1978. 6093(A)

ASSISTANT PROFESSOR BOTANY

The Department of Biology, University of Virginia is seeking candidates in the areas of molecular cellular or developmental botany an assistant professorship for September 1979. Postdoctoral experience highly desirable. By November 1, 1978 candidates should send a curriculum vitae and summary of research plan and have three letters of recommendation sent to: L. L. Rebbun, Faculty Search Committee, Department of Biology, Gilmer Hall, University of Virginia, Charlottesville, Va 229. An Affirmative Action/Equal Opportunity Employer 6094(A)

MEDICAL RESEARCH COUNCIL STATISTICIAN

The M.R.C. Clinical and Population Cytogenetics Unit, Edinburgh has an opening for a statistician with a Ph.D. or a good Honours Degree and equivalent research experience. The Unit offers extensive and varied opportunities for the application of statistical methods to the design and analysis of experiments; and in demography.

The appointment is expected to be limited to a three year term, on scale £4,365 to £5,730, though of types of contract may be considered for exceptionally well-established research statisticians.

To apply, or for further information please contact in the first instance Administrative Officer, M.R.C. Cytogenetics Unit, Crewe Road, ED BURG 4. Closing date for applications September 30, 1978. 6095(A)

**THE QUEEN'S
UNIVERSITY OF
BELFAST
POSTDOCTORAL
RESEARCH ASSISTANT
DEPARTMENT OF APPLIED
MATHEMATICS AND
THEORETICAL PHYSICS**

A postdoctoral research assistant is required to work on the theory of resonant multiphoton processes (particularly multiphoton ionisation) with Dr S. Swain. The basic requirement is a good working knowledge of quantum mechanics; experience in quantum optics would be an advantage but is not essential.

The appointment which is funded by the S.R.C. is for a period of twelve months at a salary of £3,660 (with U.S.S.).

Curriculum vitae and the names and addresses of two referees should be sent as soon as possible to the Personnel Officer, The Queen's University of Belfast BT7 1NN, N. Ireland. 7043(A)

**UNIVERSITY OF
LIVERPOOL
DEPARTMENT OF
INORGANIC, PHYSICAL AND
INDUSTRIAL CHEMISTRY
POST-DOCTORAL
RESEARCH IN POLYMER
SCIENCE**

Applications are invited for the post of Senior Research Assistant, to work with Dr G. C. Eastmond on the dynamic-mechanical properties of multicomponent polymers. Work will involve installation of equipment, establishment of experimental techniques and application to the study of molecular motions in multicomponent polymers of known chemical structure and morphology. Applicants should have relevant experience.

The post, tenable immediately, is available for a maximum period of two years. The starting salary will be £3,883 or £4,133 per annum plus U.S.S. benefits.

Applications, together with the names of two referees, should be received not later than September 29, 1978, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/921/N. 7049(A)

**MEDICAL RESEARCH
COUNCIL
TOXICOLOGY UNIT
PHARMACOLOGIST/
PHYSIOLOGIST**

required as part of a long-term programme to build up expertise for studies of the mechanism of action of toxic substances on specific organs or preparations *in vivo* and *in vitro*. He will have opportunities for interdisciplinary studies with other members of the staff as well as detailed discussions with Professor E. Zaimis of the Department of Pharmacology, Royal Free Hospital Medical School. The post will be a three-year post-doctoral temporary appointment.

Apply in writing by the end of September enclosing a full curriculum vitae to Dr W. N. Aldridge, Toxicology Unit, Medical Research Council Laboratories, Woodmansterne Road, Carshalton, Surrey SM5 4EF. 7048(A)

**ASSISTANT PROFESSOR
BOTANY**

The Department of Biology, University of Virginia is seeking candidates in the areas of molecular, cellular or developmental botany for an assistant professorship for September 1979. Postdoctoral experience is highly desirable. By November 1, 1978, candidates should send a curriculum vitae and summary of research plans and have three letters of recommendation sent to: L. I. Rebhun, Faculty Search Committee, Department of Biology, Gilmer Hall, University of Virginia, Charlottesville, Va. 22901. An Affirmative Action/Equal Opportunity Employer. 6094

**CSIRO
AUSTRALIA**

**Research Scientist or
Postdoctoral Research Fellow
Australian Numerical Meteorology
Research Centre Melbourne VIC**

CSIRO has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field:

Tropical Meteorology/Dynamic Meteorology.

General:

The Australian Numerical Meteorology Research Centre is a joint venture of the CSIRO and the Department of Science (Bureau of Meteorology). The Centre's research consists of studies of the behaviour of the earth's atmosphere, with emphasis on general circulation, directed towards improvement in the accuracy and time scale of weather forecasting, and towards improvement in understanding the distribution and variations in climate on the earth.

In this context the Centre is especially interested in developing an improved understanding of the physical mechanisms associated with interannual variability and particularly the formation and maintenance of droughts, and has an established modelling commitment directed towards this goal. The Centre is anxious to increase this commitment through the appointment of an additional scientist specialising in either the modelling of interannual variations of the large scale global circulation, or the special role of low latitude processes as a determining factor in climate variations. Access is available to the computing facilities of both the CSIRO and the Bureau of Meteorology, and a variety of large scale models developed at the Centre.

Duties:

To conduct appropriate experiments with atmospheric models consistent with the Centre's research goals, and to develop improved models suitable for studying seasonal variations of the large scale global circulation.

or

To assess through a combination of modelling experiments and observational studies the role of low latitude processes in determining variations in the large scale atmospheric circulation.

Qualifications:

Applicants should have a Ph.D. degree relating preferably to tropical meteorology or dynamic meteorology or postgraduate experience of equivalent standard and duration, supported by satisfactory evidence of research ability.

Salary:

Research Scientist: \$A14,829-\$A18,177 p.a. or Senior Research Scientist: \$A18,819-\$A21,543 p.a. Scientists with considerable experience and outstanding ability should not be deterred from applying as appointment at a higher level and salary would be considered.

Tenure:

Either: (i) an indefinite appointment as Research Scientist
or (ii) a fixed-term appointment as Post-Doctoral Research Fellow, may be negotiated. Both carry Superannuation benefits.

Applications *IN DUPLICATE*, stating *FULL* personal and professional details, the names and addresses of at least two professional referees, and *QUOTING REFERENCE NUMBER 424/28* should reach The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, LONDON, WC2R 3EH by October 7 1978.

Applications in U.S.A. and Canada should be sent to: The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., WASHINGTON, D.C., 20036, U.S.A. 7016(A)

Nature Conservancy Council (Commissioned Research - 2 year posts) Scientific Officers (8) and Higher Scientific Officers (2)

Salary: Scientific Officer £2,839*

Higher Scientific Officer £4,101

*The Officers based in London will also qualify for Inner London Weighting, ie, £485 per annum.

Applications are invited for the following contract posts in the Nature Conservancy Council, each for a fixed period of two years.

1) Invertebrate Surveys of (a) Somerset Levels and (b) Marshes in Kent and Sussex

Two survey teams are to be set up, one for each of the above areas. Each team will require two entomologists (1 freshwater and 1 terrestrial) and a botanist; one of the entomologists acting as a Team Leader (HSO) and the other two posts (SOs) in support.

2) Collation and Assessment of Species and Data for Invertebrates

Four Scientific Officers, based in Scotland (Edinburgh), Wales (Bangor) and England (2) (London) are required. Officers will not, however, work in complete isolation, as it will be necessary to have some cross flow of data, etc.

Age and Qualifications: Candidates should have a first or second class honours degree, or equivalent, preferably in botany or zoology.

Scientific Officer: Candidates should be under 27 years of age.

Higher Scientific Officer: Candidates should be under 30 years of age and have at least two years relevant postgraduate experience.

All posts involve a certain amount of travelling, therefore, possession of a current driving licence would be an advantage.

Application forms and further details are available from Miss S Jones, Recruitment Section, Nature Conservancy Council, Godwin House, George Street, Huntingdon, Cambs. PE18 8BG (Tel. 0480 56191). Closing date for completed application forms is 6 October 1978. 6063(A)

SCIENCE RESEARCH COUNCIL

FELLOWSHIPS

and

OVERSEAS (NATO) FELLOWSHIPS AND STUDENTSHIPS

Applications for SRC Fellowships and Overseas (NATO) Fellowships and Studentships commencing in 1979 should be made to the Science Research Council, PO Box 18, Swindon SN2 1ET.

For application forms telephone:

Swindon (0793) 26222, Ext. 2172

Closing date for applications:

Senior Fellowships	: November 30, 1978
Advanced Fellowships	: September 30, 1978
Postdoctoral Fellowships	: January 31, 1979
Industrial Visiting Fellowships	: Apply at any time
Overseas (NATO) Fellowships:	
In Europe	: February 1, 1979 and June 1, 1979
Outside Europe	: January 31, 1979
Overseas (NATO) Studentships	: January 31, 1979

7006(A)

GERMAN CANCER RESEARCH CENTER POSTDOCTORAL RESEARCH ASSISTANT RNA tumor viruses

The work involves studies on the mechanism of transformation by avian leukemia viruses. The salary will be about DM2,900 to DM3,100 per month for an appointment of two years. Send application with curriculum vitae and telephone number and address from two references to Dr Thomas Graf, Institut für Virusforschung, Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, 6900 Heidelberg. 7021(A)

THE MACAULAY INSTITUTE FOR SOIL RESEARCH DEPARTMENT OF SOIL SURVEY

Applications are invited for three Soil Survey Officers to work on the Survey of Scotland. Candidates should possess an Honours Degree in Geology, Soil Science, Agriculture, Chemistry or Botany.

The appointment will be in the Scientific Officer grade salary £2,839 to £4,415 per annum, according to qualifications. Non-contributory Superannuation Scheme operative.

For initial training the successful candidate may be posted to various areas in Scotland and thereafter stationed at a decentralised Soil Survey office.

Forms of application and further particulars may be obtained from The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen AB9 2QJ, to whom they should be returned before September 29, 1978 (Quote Ref. 78/24.25.26). 7047(A)

SALFORD AREA HEALTH AUTHORITY (TEACHING)

HOPE HOSPITAL,
(University of Manchester
School of Medicine),
Eccles Old Road,
SALFORD M6 8HD
RESEARCH
TECHNICIAN

required for the recently formed Department of Rheumatology. The job will involve the general running of the laboratory and assistance with research into immunological aspects of rheumatoid and other inflammatory conditions. Experience in tissue culture and/or immunological techniques would be preferred.

Salary will depend on qualifications and experience and it is hoped that the successful candidate will be appointed on the salary scale £3,261 rising to £4,680.

Application forms and job description can be obtained from the Sector Administrator Tel No 789 7373 Ext. 202 to whom they should be returned by September 15, 1978. 7037(A)

UNIVERSITY OF EDINBURGH DEPARTMENT OF MOLECULAR BIOLOGY

Applications are invited for two postdoctoral research positions. The first concerns the biochemical basis of regulation of conjugation in F-like plasmids, and is for a period of from one to three years with a starting date within the period September-December 1978. The second involves work on *Pseudomonas* plasmids and is for a period of one year beginning January 1, 1979. Salaries for both positions will be on Research Range 1A at points commensurate with age and experience.

Applications to, and further details from, Dr N S Willetts, Department of Molecular Biology, University of Edinburgh, Edinburgh EH9 3JR. Please quote Reference 5027 R. 6039(A)

UNIVERSITY OF BRISTOL DEPARTMENT OF PHYSIOLOGY

The Agricultural Research Council has awarded a

RESEARCH ASSISTANTSHIP

to the Department of Physiology for a project concerned with the mechanism of motility in mammalian spermatozoa. The work will depend principally on specialised techniques in light and electron microscopy.

Applications are invited from recent graduates who have a good Honours degree in Physiology or an associated discipline. The salary of the assistant will be on the national salary range 1B, £3,189 to £4,601 (under review). The appointment will be for 3 years and registration for a postgraduate degree will be expected. Applications, together with the names of two referees, should be sent as soon as possible to Dr D M Woolley, Department of Physiology, The Medical School, University of Bristol, Bristol BS8 1TD. 6044(A)

UNIVERSITY OF OTAGO and OTAGO HOSPITAL BOARD Dunedin, New Zealand SENIOR LECTURER IN MEDICINE

(Infectious Diseases) and
CLINICAL MICROBIOLOGY

Applications are invited for the position of Senior Lecturer in Medicine (Infectious Diseases) in the Department of Medicine, University of Otago and Consultant in Infectious Diseases and Clinical Microbiology to the Otago Hospital Board.

This is a full-time University Hospital post with University conditions of appointment and carrying hospital status in the Dunedin Hospitals.

Salary: NZ\$18,022 to \$23,302 per annum inclusive of cost-of-living adjustments. A further adjustment is pending.

To compensate for clinical responsibility, an allowance not exceeding 10% of basic salary may be paid.

Further particulars are available from the Association of Commonwealth Universities (Appa), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University, Box 56, Dunedin.

Applications close on October 31, 1978. 7063(A)

UNIVERSITY OF NATAL DEPARTMENT OF BIOCHEMISTRY Pietermaritzburg

Applications are invited from suitably qualified persons regardless of sex, religion, race, colour or national origin, for appointment to the post of

SENIOR TECHNICIAN

Experience with a range of biochemical techniques such as chromatography, electrophoresis, amino acid analysis, ultracentrifugation or radioisotope techniques, and a knowledge of biochemical instrumentation will be an advantage.

The salary scale attached to the post is:

R5,820 by 240 to R6,300 by 360 to R6,660 plus 15% per cent pensionable allowance per annum.

The commencing salary notch will be dependent on the qualifications and experience of the successful applicant. In addition, an annual vacation savings bonus is payable, subject to Treasury regulations.

Application forms, further particulars of the post and information on pension, medical aid, group insurance, staff bursary, housing loan and subsidy schemes, long leave conditions and travelling expenses on first appointment are obtainable from the Registrar, University of Natal, P.O. Box 375, Pietermaritzburg, 3200, South Africa, with whom applications, on the prescribed form, must be lodged not later than October 20, 1978, quoting reference PMB 34/78. 6067(A)

**IMPERIAL COLLEGE OF
SCIENCE AND
TECHNOLOGY
DEPARTMENT OF
BIOCHEMISTRY**

Applications are invited for two posts in a new, well-equipped research group investigating cell membrane diseases:

**1. RESEARCH
TECHNICIAN
(Grade 3)**

for biochemical investigations of erythrocyte membrane proteins, particularly those affected by hereditary spherocytosis. A sound biochemical background and previous experience in protein chemistry, electro-phoresis and chromatography are desirable. Reference DMS-RT3.

**2. RESEARCH
TECHNICIAN
(Grade 5)**

for studies involving the growth in culture of muscle cells from normal and dystrophic animals, and their preparation for electron microscopic examination by the freeze-fracture technique. Previous experience in tissue culture and/or electron microscopy is highly desirable. Reference DMS-RT5.

The appointments are initially for one year, extendable subject to continuing support from granting agencies. Starting salaries are £3,153 and £3,651 respectively, including London Weighting.

Write or telephone for an application form to the Departmental Superintendent, Biochemistry Department, Imperial College, London SW7 2AZ. (Tel. 01-589 5111 Ext. 1119, quoting the appropriate reference.

6007(A)

**UNIVERSITY OF THE
WEST INDIES—JAMAICA**

Applications are invited for the following posts:

**PROFESSOR/SENIOR
LECTURER IN PHYSICS**

The appointment to be made is in the field of Materials Science. The appointee is expected to continue to shape and teach undergraduate as well as "projected" graduate courses; he/she will also be expected to lead in the further development of research in the area of Materials Science. Industrial experience will be an advantage.

LECTURER IN ZOOLOGY

While applications are invited in any field of Zoology preference may be given to a well-qualified applicant with interests in parasitology.

Salary scales: Professor J\$17,166 to J\$21,251 p.a.; Senior Lecturer J\$12,066 to J\$16,783 p.a. (£1 sterling=J\$2.99). F.S.S.U.; Study and Travel Grant. Unfurnished accommodation will be let by the University at a rental of 10% of salary or a housing allowance of 20% of salary will be paid. Family passages. Detailed applications (2 copies) including a curriculum vitae naming three referees should be sent direct to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica, as soon as possible. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

7001(A)

RESEARCH ASSISTANT

Graduate required to join a team of scientists investigating basic aspects of cardiac biochemistry and physiology. A training in physiology or biochemistry and experience in spectrophotometry, tissue metabolite analysis or organ perfusion would be advantageous. The research unit is located in the new Rayne Institute and appointments will be made through St Thomas's Hospital Medical School.

Applications together with a curriculum vitae should be sent to Dr D. J. Hearse, The Rayne Institute, St Thomas's Hospital, London SE1. 7031(A)

SCIENCE GRADUATES— A CAREER IN EXPERIMENTAL PHYSICS?

The Vacancy

The Daresbury Laboratory has a vacancy for a young experimental physicist to assist in the preparation of equipment for the synchrotron radiation source which will commence operations during 1980. This preparatory work covers the design of beam lines for both UV and X-ray applications, the development of new instruments for the production of monochromatic radiation and the implementation of experimental programmes by Universities and other research organisations.

The man or woman appointed will be expected to take part in the practical aspects of research and development work under the supervision of experienced scientists and technical staff. A recent graduate with a first or second class honours degree in science or engineering is envisaged for this post. The appointment will be made initially at Scientific Officer level (salary in the range £2,839 - £4,415) according to qualifications and experience.

Background Information

Daresbury Laboratory is situated in a pleasant area of Cheshire and embraces a wide range of scientific disciplines. There is a well established computational science and theory group which interacts strongly with the experimental groups, and thus the person appointed will have every opportunity of developing his/her expertise and knowledge in a variety of subjects. In particular, the Synchrotron Radiation Source will be used by over 100 research teams from UK Universities for experiments in physics, chemistry and biology.

Closing date: 29 September 1978

Please write or telephone Warrington 65000, Ext. 467, for an application form quoting reference number DL/637k to:

**The Personnel Officer
DARESBUURY LABORATORY
Science Research Council
Daresbury, Warrington WA4 4AD**

6071(A)

**GRADUATE OR POSTDOCTORAL
RESEARCH ASSISTANT** required for 1½ years in the Department of Microbiology for an M.R.C. research project on cytomegalovirus immunovirology. Laboratory experience in virology essential.

Applications, with full curriculum vitae and the names of two referees, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref. M.C.2. 6076(A)

SENIOR MEDICAL LABORATORY SCIENTIFIC OFFICER

required in Medical Unit for research programme relating to kidney disease and hypertension. Applicants should be State Registered, have a knowledge of techniques used in biochemical and radio-immunological assays and be prepared to undertake biological assays.

Salary within scale £4,347 to £5,769 p.a. plus £354 p.a. London Allowance.

This is a re-advertisement and previous applicants need not re-apply.

Apply in writing with curriculum vitae and two referees to The Secretary, St. Mary's Hospital Medical School, Paddington, London W2 1PG, quoting Ref. N/S/MU. 7066(A)

Pharmacist

**Control of sterile medical products
(up to £7,525)**

The Scientific and Technical Branch of DHSS provides scientific, engineering and other professional services essential to the provision of medical apparatus, instrumentation and supplies to hospitals.

Joining a team which provides advice on, and assesses the safety and quality of, sterile medical products and devices used in the NHS the successful candidate will be concerned with the evaluation and control of sterile medical devices. Assessment covers mechanical performance, good manufacturing practice, sterilization and packaging. The work includes inspecting and advising on the manufacturing facilities in the UK and overseas and involves close liaison with medical and other professional staff in hospitals and industry.

Candidates must have a degree, or an equivalent qualification, in Pharmacy or a closely related field, and have relevant professional experience. A knowledge of plastics and familiarity with the production, assembly and packaging of sterile medical devices advantageous.

Starting salary between £6,200 and £7,525 depending on qualifications and experience. Promotion prospects. Non-contributory pension scheme.

For application form (to be returned by 28 September 1978) write to Civil Service Commission, Alencon Link, Basingstoke, Hants. RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote T/9904/3.

Department of Health and Social Security, London. 6066(A)

Applications are invited for the following post:

FACULTY OF SCIENCE — WEST HAM PRECINCT Department of Paramedical Sciences

LECTURER II IN MICROBIOLOGY WITH SPECIAL INTEREST IN FOOD MICROBIOLOGY

to teach General Microbiology and Food Science or Food Technology or Food Microbiology on the following courses.

- B.Sc. Applied Biology (Sandwich)
- B.Sc. Applied Biology (part-time)
- HNC Applied Biology
- HND Applied Biology
- B.Sc. Life Sciences (part-time)
- Other Special and Short Courses

Research on an individual or group basis will be encouraged and the successful applicant will be expected to contribute to course development.

(Temporary post available vice permanent appointment with effect from 1.9.78) (Ref. S/CF. 142)

Salary Scale:

Lecturer II: £4,101 to £6,558 per annum

Further details and application form from:

The Senior Academic Personnel Officer (2)
North East London Polytechnic
Forest Road
London E17 4JB
Telephone: 01-527 2272 (Extension 20).

Closing date: September 22, 1978.

6081(A)

UNIVERSITY OF RHODESIA CHAIR OF PHYSICS

Applications are invited for the post of Professor and Head of the Department of Physics, which will become vacant on December 31, 1978. Applicants should have held a senior university appointment in Physics and have displayed marked ability in both teaching and research. They should preferably have an interest in geophysics as well as classical physics, since much of the advanced teaching and research undertaken by the Department lies in the former area.

Salary Scale: £10,474 to £394 to £12,444 (Approx. Sig. equiv.).

Appointment will be on permanent, pensionable terms and these include: family passages and allowance towards transport of effects; installation loan of up to half of one year's salary if required; unfurnished University accommodation guaranteed for a period of at least three years for persons recruited from outside Rhodesia; sabbatical leave and biennial visits with travel allowances; superannuation and medical aid schemes.

Applications: (6 copies) giving full details of personal particulars, qualifications, experience, research, publications together with the names and addresses of three referees should be sent to the Assistant Registrar (Science), University of Rhodesia, P.O. Box MP 167, Mount Pleasant, Salisbury, Rhodesia. Overseas applicants should send an additional copy to Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF. Further particulars may be obtained from either of the above.

Closing date for receipt of applications: **September 15, 1978**, but will be accepted for a further 14 days.

British subjects considering applying for posts in Rhodesia are urged to consult the Foreign and Commonwealth Office (telephone 233 4143) or their nearest British Consular Office.

7000(A)

UNIVERSITY OF KENT AT CANTERBURY EXPERIMENTAL OFFICER/ SENIOR EXPERIMENTAL OFFICER IN ELECTRONICS

Applications are invited for the post of Experimental Officer/Senior Experimental Officer to operate and develop solid state equipment, clean air suites and a 2 Mv Van der Graaf generator in the Electronics Laboratories. Applicants should have a degree in Electronics or a related subject but other candidates with relevant experience will also be considered. Salary scales: £3,189 to £5,282 and £3,660 to £6,178.

Application forms and particulars may be obtained from the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7N1 to whom completed applications should be returned by September 29, 1978. Please quote ref: A31/78. 7034(A)

THAMES POLYTECHNIC SCHOOL OF BIOLOGICAL SCIENCES RESEARCH IN MICROBIAL GENETICS

Applications are invited from good honours graduates for the post of M.R.C. Research Assistant to Dr A. Vivian to work on the genetics of *Acinetobacter calcoaceticus*. This is a three year project funded by the Medical Research Council and the appointment is for a limited period (maximum three years). The successful applicant will be registered with the C.N.A.A. for a higher degree.

Salary: £3,015 to £3,189 inclusive. Further particulars and form of application may be obtained from the Staffing Officer, Thames Polytechnic, Wellington Street, London SE18 6PF, to whom completed applications should be returned by September 19, 1978.

6080(A)

SCOTTISH HORTICULTURAL RESEARCH INSTITUTE INVERGOWIE, DUNDEE DD2 5DA SCIENTIFIC OFFICER

A Scientific Officer is required in the Zoology Section to study the nature of tolerance in potatoes to potato cyst nematodes. Applications are invited from persons with training in plant physiology, plant pathology or nematology.

The project is financed by the Potato Marketing Board for a period of three years and the successful candidate may have the opportunity to work for a higher degree. The minimum qualification is an Upper Second Class Honours degree.

Salary: £3,294 to £3,587. Additional increments may be awarded for relevant post-qualifying experience.

Further particulars may be obtained from the Secretary of the Institute with whom applications naming two referees and stating age, education and experience should be lodged by September 30, 1978.

7044(A)

UNIVERSITY OF EDINBURGH RESEARCH FELLOW ON THE CELL CYCLE

Applications are invited for the post of Postdoctoral Fellow (Research Fellow) to work in the Department of Zoology under the direction of Professor J. M. Mitchison. The research would be on the biochemistry and genetics of the yeast cell cycle, and applicants will be favoured if they have had experience in either genetic or biochemistry of yeast.

This post is financed by a Science Research Council grant and the salary would be on the Research Range 1A starting at not more than point 3.

Applications should be sent to Professor J. M. Mitchison, Department of Zoology, West Mains Road, Edinburgh EH9 3JT, giving the names of two referees. The closing date is: September 30, 1978. Please quote reference 5021.

7056(A)

AGRICULTURAL RESEARCH COUNCIL INSTITUTE OF ANIMAL PHYSIOLOGY

Babraham, Cambridge CB2 4AT

A vacancy exists for a Scientific Officer with experience in biochemical techniques to join a small research group studying gene expression in reproductive tissues particularly with respect to the hormonal regulation of specific proteins. Research techniques will include nucleic acid hybridization and cell-free protein synthesis. Qualifications required are: Pass degree, H.N.C. or equivalent. Salary in S.O. scale (£2,839 to £4,415 p.a.) according to qualifications and experience. Non-contributory superannuation scheme. Applications to the Secretary of the Institute by September 14, 1978. Quote Ref. ARS 9.

7027(A)

FRESHWATER BIOLOGICAL ASSOCIATION WINDERMERE LABORATORY ASSISTANT LIBRARIAN/ INFORMATION SCIENTIST

Applications are invited from graduates in information science, or science graduates with a qualification in Librarianship, for the above post which is to strengthen the Association's library and information services. The post will be graded as Assistant Librarian (£3,113 to £3,579 per annum), and conditions of service will be generally similar to those of the Civil Service. Full details and application form may be obtained from the Secretary, Freshwater Biological Association, The Ferry House, Ambleside, Cumbria LA22 0LP. Closing date September 30, 1978.

7025(A)

**BIRKBECK AND IMPERIAL
COLLEGES****(University of London)
RESEARCH OFFICER IN
MOLECULAR COMPUTER
GRAPHICS**

Applications are invited for a three-year post funded by the Science Research Council to work jointly with Professor D. M. Blow and Professor T. L. Blundell in the development of interactive computer graphics for structure analysis of biological systems including proteins, drug molecules and macromolecule-water interactions.

The hardware includes an Evans and Sutherland Picture System II driven by a PDP11/60 computer linked to an IBM70/165 mainframe computer.

Applicants should have postgraduate experience in computing, structure analysis or related fields.

Salary according to qualifications and experience, within Grade 1A; entry point not exceeding £4,408 plus London Weighting £450.

Applications to Professor T. L. Blundell, Department of Crystallography, Birkbeck College, Malet Street, London WC1E 7HX, telephone no. 01-580 6622. 7002(A)

**CENTRAL
HAEMATOLOGY
LABORATORY**

Inselspital, Berne, Switzerland

Applications are invited for the post of

**RESEARCH BIOCHEMIST
(POSTDOCTORAL
RESEARCH FELLOW)**

for a period of two years from November 1, 1978. The project is concerned with the relationship between structure and function of fibrinogen or factor VIII. Candidates should have experience in biochemistry of biological macromolecules. Salary will be approximately SFR. 3,000 per month before taxes.

Applications, including a curriculum vitae and the names of two referees, should be sent to Dr M. Furlan, Hämatologisches Zentrallabor, Inselspital, CH-3010 Bern. 7050(A)

**ROCHE
RESEARCH INSTITUTE OF
MARINE PHARMACOLOGY**

invites applications for the position of

SENIOR MARINE BIOLOGIST

The Roche Research Institute of Marine Pharmacology has been established at Dee Why, N.S.W., Australia to investigate the chemistry, chemotherapy and pharmacology of natural products from marine organisms.

Applicants for the position of Senior Marine Biologist should hold a post-graduate university degree, or its equivalent, with a major specialisation in marine zoology, botany or biology, and possess an extensive knowledge of, and interest in, marine organisms and their habitat. Qualification and experience in scuba diving would be an advantage.

This appointment will be the senior position of the marine biology staff consisting of three graduate scientists. The senior marine biologist will organise and co-ordinate the collecting activities for the Roche research institute and must be able to collaborate with research scientists within the institute and with collectors in the field. The senior marine biologist may be required to spend extended periods away from Sydney, establishing areas and facilities for collection.

An attractive salary will be negotiated according to qualifications and experience. Generous superannuation benefits are available.

Applications, together with supporting statements from two referees, should be forwarded to the Director, Roche Research Institute of Marine Pharmacology, P.O. Box 255, Dee Why, NSW, 2099, by Friday, October 16, 1978. 6089(A)

R & D Management in Agrochemicals

South East England from £10,000 plus car

A Research Manager and a Development Manager are required to join the senior team directing the substantial R & D effort of one of the UK's foremost agrochemical businesses. A division of a well-known British company and part of one of the world's ten largest chemical groups, the business has a fine reputation for research-led product innovation and an impressive record of export achievement. The Division has its own excellent research facilities located in a pleasant part of South East England and has ready access to the considerable resources of the parent organisation. Both managers will report to the Research & Development Manager. There are good prospects of career progression within the company.

Research Manager

This post carries responsibility for identifying viable research topics and for the planning, direction and co-ordination of departments comprising multi-disciplinary teams. Scientists in each team are engaged in the chemical synthesis and biological testing of novel chemicals in the search for new herbicides, insecticides, plant growth regulators and fungicides which show sufficient promise to progress to the development stage. The Research Manager will also be responsible for liaison with other departments within the Division and the

maintenance of good relationships with researchers both within the parent organisation and at universities and other research establishments. Probably aged 35 or over, candidates, men or women, must have spent a minimum of 8 years in agrochemical or pharmaceutical research and have a record of successful discovery. Experience of directing the work of other scientists is essential as is the possession of a higher degree in chemistry, biochemistry or biology.

PA Personnel Services Ref: TE54/6539/N

Development Manager

Through a team of departmental heads the Development Manager will control the work of a large group of scientists and support staff. These are engaged in the field testing of active compounds to determine their efficacy and crop safety, and the appropriate method of application. Field experiments and trials are organised both in the UK and overseas and the Development Manager will be involved in regular overseas visits. Close

liaison with other senior managers in the Division is entailed. Candidates, men or women, probably aged 35 or more, must have spent at least 8 years in the agrochemicals industry and have experience in directing the work of other scientists. A degree in agriculture, chemistry, biochemistry or biology would be the minimum qualification.

PA Personnel Services Ref: TE54/6540/N

An ability to read French and German would be useful. The salary for each appointment is negotiable within a range starting at £10,000 per annum. A car is provided and the usual large company benefits apply including assistance in relocation where necessary.

Initial interviews are conducted by PA Consultants. No details are divulged to clients without prior permission. Please send brief career details or write for an application form, quoting the reference number on both your letter and envelope, and advise us if you have recently made any other applications to PA Personnel Services.

PA Personnel Services

**THE UNIVERSITY OF
MANCHESTER
RESEARCH ASSISTANT
IN PSYCHOLOGY**

Applications are invited for this post from graduates in Psychology. The work will be concerned with cognitive development in young children. The appointment will initially be for a period of two years. Salary range p.a.: £3,660 to £4,365. Superannuation. Applications, naming two referees, to M. S. Halliday, Department of Psychology, The University, Manchester M13 9PL, by September 29, 7004(A)

**UNIVERSITY
OF CAMBRIDGE
DEPARTMENT OF PATHOLOGY
TECHNICIAN**

required from November 1 for work on project involving the cultivation of trypanosomes for genetic and immunochemical studies. Qualifications HNC or equivalent. Experience of tissue culture techniques and practical biochemistry advantageous. Post funded from outside sources until September 30, 1981. Salary range £2,959 to £3,409. Applications in writing to The Superintendent, Department of Pathology, Tennis Court Road, Cambridge CB2 1QP. 6064(A)

**UNIVERSITY OF GLASGOW
DEPARTMENT OF
VETERINARY PATHOLOGY**

Applications are invited from pre or postdoctoral graduates with immunological training to work on a project concerning the immunoregulation of IgE. The position, which is on salary range 1A for research staff, is funded by the Wellcome Trust and is available immediately.

Applications and enquiries to Dr E. Jarrett, University Veterinary Hospital, Bearsden, Glasgow G61 1QH. Telephone: 041-942 2301 extension 54. In reply please quote Ref. No. 4235.

Oxford
University Press

Oxford English Dictionary Scientific Research Assistant

The Oxford University Press has a vacancy in Oxford for a full-time research assistant for *A Supplement to the Oxford English Dictionary*, now in preparation. Volume I, A-G, was published in 1972 and Volume II, H-N, in 1976. The successful applicant will undertake research in Oxford libraries into the history and usage of specific scientific terms.

Candidates should have an honours degree in a scientific subject and an interest in words and the use of library resources. A reading knowledge of German is desirable.

Salary according to age and experience on the scale £2771 - £4233, with participation in the Oxford University Press Superannuation Scheme.

Applications should be made in handwriting to L. R. Swanzy, Personnel Department, Oxford University Press, Walton Street, Oxford OX2 8DP by 30 September 1978, with the names and addresses of two referees.

7041(A)

EUROPEAN MOLECULAR BIOLOGY LABORATORY

MOLECULAR COMPUTER GRAPHICS

Applications are invited for a post in the Instrumentation Division to develop interactive computer graphics software for macromolecular structure analysis and other biological problems. Applicants must have interest and experience in development, maintenance and documentation of a library of advanced computer programs and should also be familiar with crystallographic computing, theoretical chemistry (for example molecular dynamics), or interactive computer graphics.

Hardware includes an Evans and Sutherland Picture System II driven by a 128 K-word minicomputer. Access to a remote DEC 1090 and to an Amdahl 470/IBM 360-91 system is also available. Present software includes an extension of the Diamond interactive molecular graphics system.

Salary, according to qualifications and experience, within range DM 3400 and DM 4000 monthly, after tax. Removal costs and, where appropriate, expatriation and other allowances, will be paid.

Applications, quoting reference No. 78/28, and including a curriculum vitae, brief statement of research interest and the names of referees should be sent to:

Sir John Kendrew
Director General
EMBL
Postfach 10.2209
D - 6900 Heidelberg
Germany

6095(A)

QUEEN ELIZABETH COLLEGE Kensington

(University of London)
DEPARTMENT OF FOOD
SCIENCE AND NUTRITION

RESEARCH STUDENTSHIP

Applications are invited for a Research Studentship, sponsored by a major food manufacturer, to work with Dr Stuart Thorne on a feasibility study of a novel food preservation process. Applicants should have a good, relevant honours degree, some mathematical ability and an interest in unsteady state heat and mass transfer. The successful candidate will be expected to spend some time at the sponsor's premises.

The studentship is tenable for two years in the first instance and may be renewed for a third year. Support will be at the same rate as the student would receive from a Research Council, and travelling and subsistence allowances whilst working at the sponsor's premises will be given.

Applications, including a brief curriculum vitae and the names and addresses of two academic referees should be sent to Dr S. N. Thorne, Queen Elizabeth College, Campden Hill Road, Kensington, London W8 7AH, by September 30, who may also be contacted informally (01-937 5411 extn 238).

7054(A)

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF GEOLOGICAL SCIENCES LECTURER

IN HYDROGEOLOGY

Applications are invited for the above post, the duties of which will principally include the teaching of Hydrogeology at M.Sc. Course level and the supervision of Course project work. The successful applicant will be expected to pursue research in the field of hydrology.

Applicants should have a good honours degree. A postgraduate qualification in Hydrogeology and practical experience would be advantageous.

Salary according to age and experience, in the range £3,660 to £7,308 (to be reviewed from October 1) plus superannuation.

Further particulars are available from the Assistant Registrar, Science and Engineering, University of Birmingham, PO Box 363, Birmingham B15 2TT, to whom applications (3 copies) including curriculum vitae and the names of three referees should be sent by Friday, October 20, 1978. Please quote reference NG6

6073(A)

DIRECTOR of the proposed CRUMP INSTITUTE OF MEDICAL ENGINEERING AT U.C.L.A.

Applications are invited for consideration by the Search Committee for the Director of the proposed "Crump Institute for Medical Engineering" at U.C.L.A.

A new building is being planned, a Chair has been endowed for the Director, and private and University core support has been pledged. This position represents a unique opportunity to contribute to the development of the evolving field of "medical engineering," and to establish a major Medical Engineering Programme at U.C.L.A.

Qualifications: A person of exceptional ability, accomplishments, and international stature is sought whose work and interests bear on the interface between engineering and medical sciences. Demonstrated scientific productivity, leadership and administrative abilities are desirable.

Responsibilities: To administer and direct the proposed Institute.

Salary: Commensurate with qualifications and experience.

Equal Opportunity: The University of California is an equal opportunity employer.

Send resume to Dr Frederick Allen, Chairman, Search Committee, School of Engineering and Applied Sciences, 7714 Boelter Hall, U.C.L.A., Los Angeles, CA 90024.

6098(A)

UNIVERSITY OF WARWICK POSTDOCTORAL RESEARCH FELLOW

Applications are invited for a one year Postdoctoral Research Fellowship in the Department of Chemistry and Molecular Sciences to work on the photochemistry of metal complexes in the solid state with Drs N. W. Alcock and T. J. Kemp. The project will involve synthesis, photochemistry and X-ray diffraction and would be suitable for someone with expertise in one of these fields (particularly the first) wishing to extend their range of skills. The post is available immediately. Initial salary will be on one of the first three points of the Research Range 1A scale: £3,660 (£4,130) to £6,178 p.a. (under review).

Applications (including a detailed curriculum vitae and the names of two referees) to the Academic Registrar, University of Warwick, Coventry CV4 7AL by October 6, 1978. Please quote Ref No. 3/A/78. 6072(A)

HEINRICH PETTE- INSTITUT

für Experimentelle Virologie
und Immunologie an der
UNIVERSITÄT HAMBURG

Applications are invited for the position of

HEAD OF THE DIVISION OF IMMUNOLOGY

The Institute consists of six divisions. It is a foundation concerned with research on the biology of human viruses, the pathogenesis of virus diseases, and defence mechanisms of the host and related problems.

We are looking for a scientist whose main interest lies in the field of cell biology and/or virology.

Curriculum vitae, list of publications, and further documents should be sent to the Board of Directors of the Heinrich Pette-Institut, Martinstrasse 52, D-2000 Hamburg 20, Federal Republic of Germany, by November 1, 1978. 6092(A)

MASSEY UNIVERSITY Palmerston North, New Zealand LECTURER/SENIOR LECTURER IN PIG HUSBANDRY AND DIRECTOR OF PIG RESEARCH CENTRE

Applications are invited for the above mentioned position. The successful applicant will become a member of the Dairy Husbandry Department responsible to the Head of that Department, for teaching and to the Vice-Chancellor, for the Pig Research Centre.

At present pig production courses involve about one hundred hours of undergraduate teaching annually plus postgraduate student teaching and supervision.

The Pig Research Centre has a staff of one Research Officer and three permanent stockmen. The Director reports to the University Farms Committee, a subcommittee which is made up of University Council Appointees and New Zealand Pork Industry Council members. The Centre is a University Facility, funded jointly by the Pork Industry Council, the Ministry of Agriculture and Fisheries, and the University.

Salary: Senior Lecturer NZ\$13,424 to NZ\$15,411; Lecturer NZ\$10,585 to NZ\$12,969.

Further details of the position together with the conditions of appointment may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or the Registrar of the University. Applications close on September 29, 1978. 7008(A)

UNIVERSITY OF
MELBOURNE
LECTURESHIP IN THE
SCHOOL OF PHYSICS

Applications are invited for a continuing Lectureship position in the School of Physics. The current research interests of the School are high energy physics, diffraction physics, low energy nuclear physics and theoretical physics.

The successful applicant will be required to teach at an undergraduate level by lecturing or supervising laboratory classes, to supervise research students and to conduct research in one of the above areas of physics.

QUALIFICATIONS Ph.D. with postdoctoral experience.

SALARY \$A15,179 to \$A19,940 per annum.

The position can be taken up on January 16, 1979, or as soon as possible thereafter.

Further information, including details of application procedure and conditions of appointment, is available from the Registrar, University of Melbourne, Parkville, Victoria, Australia 3052, or from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF. Applications close October 31, 1978.

7064(A)

CHELSEA COLLEGE
University of London

A POSTDOCTORAL RESEARCH ASSISTANT is required to join a group working on biological membranes. Particular experience in the biophysical aspects of the subject would be an advantage. The post is supported by the Muscular Dystrophy Association and the appointment will be for one year in the first instance to commence as soon as possible. Salary in the range £3,660 to £4,130 per annum plus £450 London Allowance.

Application forms and further details from the Personnel Officer, Chelsea College, Friesse Greene House, Chelsea Manor Street, London SW3 3TW. Closing date September 25, 1978.

7042(A)

DEAKIN UNIVERSITY
Geelong, Australia
SCHOOL OF SCIENCES
LECTURER IN PHYSIOLOGY
Ref: 78/1/12

Applications are invited from suitably qualified people for the above-mentioned position.

In 1979 the University will have about 4,000 students, of which about half will be enrolled in off campus courses. The main campus of the University is on an 80 hectare site at Warrn Ponds, 8 kilometres south west of Geelong.

A fixed term appointment is normally for period of three years. Although an appointment may be extended for a further three years it cannot be translated into a permanent appointment.

Current Salary Range \$A15,179 to \$A19,940 per annum.

The Division of Biological and Health Sciences offers undergraduate major programs in biology, biochemistry, nutrition and food chemistry, a graduate diploma of dietetics, and participates in the teaching of a graduate diploma of industrial hygiene. Present research interests of the Division are in the areas of toxicology, endocrinology and nutrition.

The appointee will assist with the lecturing in undergraduate physiology and biochemistry courses, with a major emphasis on physiology. Applicants should possess a doctorate in an appropriate discipline and have some tertiary teaching experience. The appointment is offered on a fixed term (three years) basis to commence on January 1, 1979.

Applications (quoting reference number) should include a full curriculum vitae and the names and addresses of three academic referees, and should be sent to reach the Staff Officer at P.O. Box 125, Belmont, 3216, Victoria, Australia by October 1, 1978. Applicants resident in North America, Europe or Africa should also send a copy of their applications to the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF, from whom further details about the position can be obtained.

7064(A)

AUSTRALIAN INSTITUTE OF MARINE SCIENCE

Applications are invited for the following position in research at the Australian Institute of Marine Science (A.I.M.S.), which is situated on a 190 hectare site at Cape Ferguson near Townsville, North Queensland, and projects development into one of the foremost institutions in the world in the field of tropical marine science. Facilities include a 12.8 million dollar headquarters and comprehensively equipped laboratory complex, library, lecture theatre, controlled environment rooms and aquaria, accommodation for visiting scientists, and various field and technical support facilities such as a deepwater boat harbour, recompression chamber, and maritime services building.

Initial research at A.I.M.S. has been concentrated in three main areas:

- (I) Tropical marine food webs
- (II) The Great Barrier Reef and its Reef-building organisms
- (III) Tropical marine pollution.

The existing fleet of small vessels will shortly be augmented substantially, with the delivery of a 26m research vessel built specifically for A.I.M.S.

Further major expansion is planned, and will assure challenging research growth in tropical marine science.

BIOLOGICAL OCEANOGRAPHER

Duties: To plan and execute field/laboratory programmes devoted to a fuller understanding of the structure, function and dynamics of pelagic food webs, especially within coastal and oceanic waters of the tropics. Consideration of likely interactions with shallow benthic and land-sea interface systems are viewed as potentially significant.

Qualifications: A Ph.D. degree or equivalent qualifications in the field of biological oceanography with evidence of substantial contribution in research and experience in the management of programmes at sea and ashore. A specific area of interest is not pre-requisite, however, the individual selected must be equipped to view his or her responsibilities with perspective within the broad limits of the discipline.

Appointment will be made within the Senior Research Scientist range (\$A18,819-\$A21,545), depending on qualifications and experience. Appointment at a higher level may be considered in exceptional circumstances.

It is envisaged that the successful applicant will be required to take up appointment on April 1, 1979.

Further information on A.I.M.S. and general employment conditions will be supplied on request.

Application must include a full c.v., plus the names and addresses of three professional referees, and should be sent to:

The Secretary, Australian Institute of Marine Science, P.M.B. No. 3, TOWNSVILLE, M.S.O. 4810

Closing Date for applications is October 20, 1978.

7017(A)

QUEEN'S MEDICAL CENTRE
UNIVERSITY OF
NOTTINGHAM
DEPARTMENT OF
BIOCHEMISTRY

A RESEARCH TECHNICIAN is required to assist on a research funded project on the biochemical mechanism and control of the biosynthesis of fungal wall polysaccharides and glycoproteins. The appointment is available from October 1, 1978 and is available for one year in the first instance. The post is on the Whitley Scale and commences at a salary of £3,261 rising to a maximum of £4,680 depending on age, qualifications and experience. The successful applicant is expected to have experience and/or interest in standard microbiological and biomedical techniques.

Application forms from Mr F. C. Treeby, Chief Technical Adviser, Medical School, Queen's Medical Centre, Nottingham NG7 2UH

6082(A)

NATAL MUSEUM
Pietermaritzburg, South Africa
VACANCY FOR A
DIPTERIST

Applications are invited for a vacancy in the Department of Entomology at the Natal Museum. The appointee will be required to take charge of the Department and undertake taxonomic research on Diptera. A person interested in one of the families Tachinidae, Cecidomyiidae, Dolichopodidae or Phoridae, is particularly sought, but applicants with other interests will also be considered. The minimum academic requirement is an Honours degree. Full details of the post and application forms can be obtained from the Director at 237 Loop Street, Pietermaritzburg 3201, South Africa.

7033(A)

PORTSMOUTH
POLYTECHNIC
DEPARTMENT OF GEOLOGY
LECTURER II/
SENIOR LECTURER

Structural Geologist preferably with experience and interest in Engineering Geology to teach B.Sc. (Honours) courses and undertake research. From January 1, 1979.

Salary scale: £4,101 to £6,051 (efficiency bar) to £7,572 per annum.

Further particulars and application forms from the Staff Officer, Portsmouth Polytechnic, Alexandra House, Museum Road, Portsmouth PO1 2QQ to whom completed applications should be returned by September 19, 1978. Please quote ref: X12 6083(A)

EUROPEAN MOLECULAR BIOLOGY LABORATORY

X-RAY CRYSTALLOGRAPHER

Applications are invited for a post in the Biological Structures Division to study macromolecular structure using X-ray diffraction. Applicants should have experience in crystallographic computing, crystallography of macromolecules, or X-ray diffraction analysis of semicrystalline materials such as fibres.

The research programme includes studies of structures involved in the mechanism and control of DNA replication, in membrane function, and in virus assembly, especially using the filamentous bacterial virus system as a model.

Salary, according to qualifications and experience, within range DM 3400 and DM 4000 monthly, after tax. Removal costs and, where appropriate, expatriation and other allowances, will be paid.

Applications, quoting reference No. 78/28, and including a curriculum vitae, brief statement of research interests and the names of referees should be sent to:

Sir John Kendrew
Director General
EMBL
Postfach 10.2209
D — 6900 Heidelberg

LADY DAVIS FELLOWSHIP TRUST

P.O. Box 1255, Jerusalem, Israel

FELLOWSHIPS FOR STUDY AND/OR RESEARCH AT GRADUATE OR POSTGRADUATE LEVELS AND VISITING PROFESSORSHIPS

in 1979–80

at the Hebrew University of Jerusalem and at the Technion—
Israel Institute of Technology, Haifa

GRADUATE AND POSTDOCTORAL FELLOWSHIPS

Eligibility: Lady Davis Fellows will be selected on the basis of demonstrated excellence in their studies, promise of distinction in their chosen fields of specialisation and qualities of mind, intellect and character.

Postdoctoral candidates shall have completed their doctoral dissertation (before arrival in Israel).

The Graduate and Postdoctoral Fellowships are tenable for a period of one year. They may be renewed for a second year and in special circumstances extended to a third year.

The grant is intended to defray the cost of the Fellow's travel and tuition fees and to meet reasonable living expenses.

Application: Graduate candidates may apply during their senior academic year or after they have undertaken study in a graduate school. Postdoctoral candidates may apply at an early stage of their professional career (not later than three years after completion of their doctoral dissertation).

Graduate and Postdoctoral candidates (including Israelis abroad) may obtain application forms from the Lady Davis Fellowship Trust at the above address, after they indicate the category of Fellowship for which they are eligible.

Completed applications must reach the office of the Trust not later than January 1, 1979.

VISITING PROFESSORSHIPS

These Fellowships are intended for candidates with the rank of Full or Associate Professor at their own institution. They are tenable for periods from one trimester (or semester) to a year.

Application: Forms may be obtained from the Lady Davis Fellowship Trust at the above address. Completed application forms for the Hebrew University must reach the office of the Trust by November 30, 1978. Those for the Technion by December 31, 1978.

7045(A)

BASIC GRADE BIOCHEMIST FACULTY OF MEDICINE DIAGNOSTIC RESEARCH UNIT SOUTHAMPTON GENERAL HOSPITAL

A biochemistry graduate is required to assist in the development of diagnostic methods for use in hospital biochemical laboratories. Appointment one year in the first instance. Salary: £3,486 to £4,275 per annum according to relevant experience. Application forms and job description from District Personnel Department, Tremona Court, 30-32 Tremona Road, Southampton. Telephone: 777222, Ext. 3556 or 3018. Further information from Dr F. G. Bull, Telephone: 777222, Ext. 3910. Closing date: September 21, 1978.

6085(A)

UNIVERSITY OF SURREY DEPARTMENT OF BIOCHEMISTRY LECTURER IN BIOCHEMISTRY

Applications are invited from suitably qualified graduates for a Lectureship in Biochemistry in the Department of Biochemistry. Preference will be given to applicants with postgraduate experience and to those with an interest in pharmacological biochemistry. Industrial experience would also be considered advantageous.

Salary will be within the range £3,660 to £7,308 per annum according to qualifications and experience. Superannuation will be under U.S.S. conditions.

Further particulars about the post may be obtained from the Academic Registrar (LFG), University of Surrey, Guildford, Surrey GU2 5XH or Tel. Guildford 71281, ext. 452. Applications from men and women in the form of a curriculum vitae, together with the names and addresses of two referees, should be sent to the above by September 29, 1978.

6070(A)

NEUROSCIENCES FACULTY

Faculty positions available in the Neurosciences Program, Maryland Psychiatric Research Center, affiliated with the University of Maryland School of Medicine. One position is open to a

SCIENTIST

with rigorous postgraduate training in neuroendocrinology, basic expertise in hormone assay procedures and the capability to study functional aspects of hormones/polypeptides in a multidisciplinary clinical research centre. The second position is for a SCIENTIST with rigorous postgraduate training in a neurobiology specialty with preference given to strength in biochemistry and/or genetics plus experience in cell or organ culture techniques.

Submit curriculum vitae, summary of research interest and two letters of reference by November 15, 1978, to: Neurosciences Search Committee, Maryland Psychiatric Research Center, Box 3235, Baltimore, Md. 21228. An Equal Opportunity Employer.

7060(A)

UNIVERSITY OF WARWICK RESEARCH ASSOCIATE

in the

DEPARTMENT OF CHEMISTRY AND MOLECULAR SCIENCES

Applications are invited for the post of RESEARCH ASSOCIATE with Dr B. E. P. Swoboda to study the detailed mode of action of the anti-tumour agent, cyclophosphamide on normal and cancer cells. Some experience with cell culture, organic syntheses and/or radioisotope techniques would be advantageous and the applicant should have a good degree in Biochemistry or a related subject.

The appointment, which is supported by the Cancer Research Campaign, is initially for one year, with the possibility of extension to three years. Maximum starting salary will be £3,660 per annum on Research Range 1B, plus superannuation. Applications (two copies) giving qualifications and experience and naming two referees should be sent to the Academic Registrar, University of Warwick, Coventry CV4 7AL, as soon as possible, quoting Ref. No. 4/2A/78.

6084(A)

THE LONDON HOSPITAL MEDICAL COLLEGE (University of London) DEPARTMENT OF BIOCHEMISTRY RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant in the Department of Biochemistry. The post will be tenable for a period of two years with effect from October 1978.

The project with which the successful applicant will be associated concerns the immunochemical aspects of human lysosomal enzymes in relation to two lysosomal storage disorders, Tay-Sachs disease and Gaucher's disease. The project is funded by the Mental Health Foundation.

Candidates should have a B.Sc. degree in biochemistry as well as appropriate practical experience and an interest in the field of human lysosomal enzymes. It is unlikely that there will be the opportunity to study for a higher degree.

Salary: The basic salary will be £3,384 plus £450 London Allowance per annum together with superannuation under the U.S.S.

Apply in the first instance with a curriculum vitae and the names and addresses of two academic referees to: Dr Mark Carroll, Department of Biochemistry, The London Hospital Medical College, Turner Street, LONDON E1 2AD.

7003(A)

UNIVERSITY OF SURREY DEPARTMENT OF BIOCHEMISTRY READER IN NUTRITION

Applications are invited for the position of Reader in Nutrition in the Department of Biochemistry. The person appointed will contribute to the undergraduate and postgraduate teaching within the Department and be responsible for the initiation and supervision of research.

Applicants must be graduate with a higher degree and a good research record. Preference will be given to those with an interest and experience in clinical nutrition. A medical qualification would be an additional recommendation.

Salary will be within the range £7,074 to £8,730 per annum according to qualifications and experience. Superannuation will be under U.S.S. conditions.

Further particulars about the post may be obtained from the Academic Registrar (LFG), University of Surrey, Guildford, Surrey GU2 5XH or Tel. 71281, ext. 452. Applications from men and women in the form of a curriculum vitae, together with names and addresses of three referees, should be sent to the above by September 29, 1978.

6069(A)

UNIVERSITY OF ASTON IN BIRMINGHAM DEPARTMENT OF GEOLOGICAL SCIENCES

Applications are invited for two new posts as

LECTURER IN GEOLOGY

Candidate for the first post should have active research interests in the field of igneous petrology, preferably involving rocks of Mesozoic or later age.

The second post is open to active research workers in any field of geology. It is unlikely, however, that the post will be given to a specialist mineralogist or palaeontologist.

Possession of a Ph.D. degree is a condition of appointment, but young research workers who anticipate the award of a doctorate by November 1978 may apply.

Commencing salary will be within the range £3,883 to £5,842 p.a. on a scale rising by annual increments to £7,754 per annum. (Under review).

Preliminary information about these posts may be obtained from Professor D. D. Hawkes (Tel. 021 359 3611 Ext. 568) at the following address. Application forms and further details may be obtained from the Staff Officer (Ref. 290/6) University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET (Tel. Ext. 201) to whom applications should be forwarded not later than Friday, September 29, 1978.

6079(A)

M.R.C. CLINICAL RESEARCH CENTRE
(Northwick Park Hospital)
Watford Road, Harrow,
Middx. HA1 3UJ

**APPOINTMENT OF
HEAD OF DIVISION OF COMPUTING AND STATISTICS**

The Medical Research Council invites applications for the post of head of the division of computing and statistics at the Clinical Research Centre, Harrow, Middx.

The person appointed will be required to direct the division's research programme, to maintain a computing and statistical service for the Clinical Research Centre, and also to maintain a close association with the Northwick Park Hospital Computing Service. The future research programme will be a matter for discussion between the new head of the division and the director of the centre, taking into account the particular interests of the selected candidate and the needs of the centre.

Candidates should be of a high scientific standing and with proven ability in managing a research team.

The salary will be within the range for the council's special appointments grade which is equivalent to the universities' professorial range.

Further information about the appointment may be obtained from the Director, Clinical Research Centre, Watford Road, Harrow, Middlesex HA1 3UJ. Ref. 109/1/4079. The final date for the receipt of application is November 3, 1978. 7061(A)

**UNIVERSITY OF
ST ANDREWS**
DEPARTMENT OF ANATOMY
AND EXPERIMENTAL
PATHOLOGY

Applications are invited for the recently allocated post of LECTURER in the Department of Anatomy and Experimental Pathology. The successful candidate will be expected to contribute to the courses that are provided for pre-clinical students and for science students. Excellent facilities for research are available. The department may be visited by arrangement with Mrs Norton (telephone Andrews 2411).

Salary at appropriate point on scale 3,660 to £7,308 (under review), starting salary probably not above £5,282. S.S.U./U.S.S.

Applications (two copies preferably, typed) with the names of three referees should be sent by September 2, 1978 to the Establishments Officer, The University, College Gate, St Andrews, Fife, from whom further particulars may be obtained. 7013(A)

**THE WEST OF SCOTLAND
AGRICULTURAL COLLEGE**
SENIOR LECTURER/
ADVISED IN POULTRY
HUSBANDRY

Applications for the post are invited from holders of a suitable degree or a nationally recognised diploma with considerable relevant experience. The duties will include formal teaching of 11-time students, advisory work for the poultry industry and related research/development activity.

The salary will be on Grade II, £4,477 to £7,651 per annum. Further particulars and application forms may be obtained from the Secretary, The West of Scotland Agricultural College, Ochmercurie, Ayr KA6 5HW, with whom applications should be lodged at later than October 20, 1978. 7036(A)

**THE UNIVERSITY OF
SHEFFIELD**
DEPARTMENT OF METALLURGY
POSTDOCTORAL
RESEARCH ASSISTANT
(S.R.C.)

Physicist, chemist, chemical engineer, metallurgist or materials scientist (man or woman) required for light-scattering studies on aerosol condensation using visible and infrared laser radiation. Initial salary in range £3,660 to £4,365 according to qualifications and experience, with superannuation. Tenable 2 years. Curriculum vitae with names and addresses of two referees to Dr E. R. Buckle, Department of Metallurgy, the University, Sheffield S1 3JD. Quote ref. R194/G-7015(A)

**BRIGHTON
POLYTECHNIC**
FACULTY OF NATURAL
AND LIFE SCIENCES
DEPARTMENT OF
PHARMACY
RESEARCH
ASSISTANTSHIPS

Vacancies exist for Research Assistants in the following areas:-
(1) Medicinal Chemistry — synthesis of heterocyclic compounds of potential biological interest.

(2) Microbiology — the production of exoenzymes and peptide antibiotics in sporulating cultures of *Bacillus* species.

Salary scale £2,613 by £87 (2) to £2,787.

Details of posts and application forms from Administrative Officer, Faculty of Natural and Life Sciences, Brighton Polytechnic, Moulsecoomb, BRIGHTON BN2 4GJ, to whom completed forms should be returned by September 18, 1978. 7027(A)

**THE LADY DAVIS
INSTITUTE FOR
MEDICAL RESEARCH**
JUNIOR STAFF POSITION
AVAILABLE

Ph.D. or M.D. with at least 2 years postdoctoral research experience. Will be responsible for establishing an independent research program. The current activities at the Institute include studies on cancer (cell growth control, nutrient transport, gene regulation, hormone receptors), control of protein synthesis, lymphocyte function, diabetes, somatic cell genetics and aging. The interests of candidates may relate to but need not be confined to these topics. Send curriculum vitae with short description of research proposal (long term objectives, immediate goals, research plan and significance of proposed work) to Director, Lady Davis Institute for Medical Research, Jewish General Hospital, 3755 Cote Ste Catherine Road, Montreal, Quebec H3T 1E2. Closing date October 31, 1978. 7030(A)

**UNIVERSITY OF
NOTTINGHAM**
GENETICS RESEARCH UNIT
RESEARCH TECHNICIAN
GRADE 3

This post involves helping in a research project, financed by the Medical Research Council, on the genetic control of enzyme synthesis in the fruit fly. Minimum educational requirements: O.N.C., O.N.D. or equivalent. Credit will be given for H.N.C., H.N.D. or degree. Experience in biochemical techniques is desirable. The appointment is for two years at a salary in the range £2,638 to £3,060, according to age and experience.

Applications, including a curriculum vitae, giving details of qualifications and experience and the names of two referees should be sent to Professor Bryan Clarke, Genetics Research Unit, Queen's Medical Centre, Clifton Boulevard, Nottingham NG7 2UH before October 15, 1978. 7020(A)

**THE UNIVERSITY
OF MANCHESTER**
GEORGE HARRISON
CHAIR OF BOTANY

Applications are invited for the George Harrison Chair of Botany which will fall vacant on October 1, 1979 on the retirement of Professor D. H. Valentine. The other Chair in Botany is the Barker Chair of Cryptogamic Botany which is held by Professor John Colhoun. Particulars of the Appointment may be obtained from the Registrar.

Applications (2 copies, 1 suitable for photocopying), giving full details of qualifications, experience, research etc., and the names and addresses of three persons to whom reference may be made, should be sent to the Registrar, The University, Manchester M13 9PL by October 18, 1978. 6067(A)

CLEMENT ASSOCIATES, INC.

consultants in the environmental and health-related sciences, is seeking specialists in the following disciplines:

- Chemistry
 - *organic chemistry
 - *environmental chemistry
- Biology
 - *biochemistry
 - *toxicology
 - *pharmacology
- Environmental Sciences
 - *ecology
 - *air and water pollution control
- Occupational Health
 - *industrial hygiene
 - *chemical engineering
- Medicine

A graduate degree is required and a doctorate preferred. Clement is a leading firm in the fields of human and environmental health. We offer excellent salaries and comprehensive benefits. Applications and inquiries should be sent to:

CLEMENT ASSOCIATES INC.
Scientific Regulatory Consultants
1010 Wisconsin Avenue, N.W. Suite 660
Washington, D.C. 20007
Marie Baumann, Personnel Director
7029(A)

BIOCHEMIST/MICROBIOLOGIST

Bush Boake Allen Ltd., a division of Albright & Wilson, have a vacancy for a Biochemist/Microbiologist to work in their microbiological research laboratory, based at Walthamstow, London E.17.

The successful candidate will join a team whose duties are to study the secondary metabolites produced by micro-organisms for use in perfumery and flavour products.

Applicants aged between 22-30 should have a degree in biochemistry or microbiology with at least one or two years research experience in the field of microbial biochemistry. Experience in gas chromatograph analysis, the extraction of natural products from micro-organisms and/or studies in intermediary metabolism will be a distinct advantage.

An attractive salary will be offered in addition to a range of employee benefits which include a non-contributory pension scheme. Applications in writing to:

R. J. Saunders,
Recruitment and Training
Manager,
Bush Boake Allen,
Blackhorse Lane,
London, E.17

stating age, qualifications and
experience. 7032(A)

Bush Boake Allen

UNIVERSITY COLLEGE GALWAY

JUNIOR LECTURESHIP IN GEOLOGY

Applications are invited for the above post. Salary scale £4,757 x (10) — £6,575. Closing date for receipt of applications 6 OCTOBER 1978. Further information may be obtained from the Registrar. 7014(A)

**Centre for Overseas Pest Research,
London**

Scientific Librarian

■ Take responsibility for periodical literature and exchange material ■ Scan, catalogue and index scientific literature including foreign language material ■ Answer readers' enquiries.

□ Good hon's degree or equivalent in a Biological Science or Agriculture or closely related subject □ Postgraduate librarian training essential □ Aptitude for languages advantageous □ Age normally under 27 □ Appointment as Scientific Officer (£3300-£4880) □ Ref: SA/47/JA.

■ Application forms (for return by 28 September 1978) from Miss M Cole, Centre for Overseas Pest Research, College House, Wrights Lane, London W8 5SJ.

**Science
Group**
CIVIL SERVICE

THE CALIFORNIA INSTITUTE OF TECHNOLOGY

invites applications for a
JUNIOR FACULTY
POSITION IN ASTRONOMY

The major research interests of candidates should be in observational optical or infrared astronomy. The position is an assistant professorship; however, in exceptional circumstances the successful candidate may be offered an associate professorship.

Members of the Caltech Astronomy Faculty whose major research activity is in optical or infrared astronomy are normally appointed as Staff Members of the Hale Observatories subject to the approval of the California Institute and of the Carnegie Institution of Washington.

Applications should include (1) a description of educational background; (2) a résumé of research and teaching experience; (3) a list of all publications; (4) copies of all manuscripts submitted for publication but not yet published; (5) a statement of current research interests and future research plans. The applicant should ask three scientists who know the applicant personally to send letters of evaluation directly to Professor W. L. W. Sargent, Executive Officer for Astronomy, California Institute of Technology, Pasadena, CA 91125. Completed applications and letters of evaluation should be received by November 1, 1978; appointment will be made as soon thereafter as circumstances permit.

Caltech is an Equal Opportunity Employer with an Affirmative Action Program. We encourage applications from qualified women, members of minority groups and persons with non-disqualifying handicaps. 6097(A)

MEAT RESEARCH INSTITUTE SCIENTIFIC OFFICER/ HIGHER SCIENTIFIC OFFICER

to conduct analytical, biochemical and endocrine studies with laboratory and meat animals.

The objective is to define and identify the means of manipulating those sub-cellular mechanisms of sex steroid action, which lead to sex-dependent patterns of somatic development.

Qualifications: Pass degree, H.N.C. or equivalent with experience or an honours degree in biochemistry or physiology. At least five years post-qualifying experience is normally required for appointment to the higher grade.

Salary:
S.O.—£2,592 to £4,032.
H.S.O.—£4,101 to £5,448.

Starting salary depending on experience. Permanent, pensionable post.

Closing date for applications: September 22, 1978.

Application forms: Personnel Officer, Meat Research Institute, Langford, Bristol BS18 7DY. 7052(A)

UNIVERSITY OF SURREY DEPARTMENT OF BIOCHEMISTRY LECTURER IN FOOD SCIENCE

Applications are invited from suitable qualified graduates for a Lectureship in Food Science in the Department of Biochemistry. Preference will be given to applicants with postgraduate experience, and industrial experience would also be advantageous.

Salary will be within the range £3,660 to £7,308 per annum according to qualifications and experience. Superannuation will be under U.S.S. conditions.

Further particulars about the post may be obtained from the Academic Registrar (LFG), University of Surrey, Guildford, Surrey GU2 5XH or Tel. Guildford 71281, ext. 452. Applications from men and women in the form of a curriculum vitae, together with the names and addresses of two referees, should be sent to the above by September 29, 1978. 6068(A)

WELSH NATIONAL SCHOOL OF MEDICINE AND UNIVERSITY OF SUSSEX POSTDOCTORAL RESEARCH OFFICERS

Applications are invited for two research posts, funded by the Medical Research Council, to work on a three-year collaborative project between Dr F. McCapra, Department of Chemistry, University of Sussex and Dr A. K. Campbell, Department of Medical Biochemistry, Welsh National School of Medicine. The project is entitled "Biomedical applications of chemi- and bioluminescence". It concerns the synthesis and biochemical characterisation of the prosthetic group of Ca^{2+} -activated photoproteins, luminescent labels of proteins as a substitute for radioactive labelling and luminescent reagents for biochemical studies in intact cells. Further particulars of the posts are available from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN (quoting ref. No. C38/4/24).

Applicants should have completed their studies for a Ph.D. and preferably have experience in either organic synthesis or biochemistry. Starting salary can be up to £4,130 on Grade 1A for University Research and Analogous Staff.

Applications should be sent by October 1, 1978 both to the Registrar and Secretary of the Welsh National School of Medicine (address as above) and to Dr F. McCapra, Department of Chemistry, School of Molecular Sciences, University of Sussex, Falmer, Brighton, Sussex BN1 2QJ and should take the form of a curriculum vitae plus the names and addresses of two referees. 7012(A)

UNIVERSITY COLLEGE LONDON DEPARTMENT OF BIOCHEMISTRY

Applications are invited for two LECTURER posts in the Department of Biochemistry. Starting date by mutual agreement. Applicants should be graduates in Biochemistry or Molecular Biology with postdoctoral experience. They should possess the capacity to initiate their own research programmes and be prepared to contribute fully to the teaching programme of the Department. Excellent facilities for research are available. Salary according to age and experience within the range £3,883 to £7,754 p.a. plus £450 London Allowance. Applications including full curriculum vitae, list of publications and names of two academic referees should be sent by the end of October to Professor B. R. Rabin, (N), Department of Biochemistry, University College London, Gower Street, London WC1E 6BT. 7035(A)

UNIVERSITY OF THE WEST INDIES—TRINIDAD

Applications are invited for the post of SENIOR LECTURER/LECTURER in PHYSICS. Must have specialisation preferably in the fields of Optics including Infrared Optics and thin Films, or in High Energy Nuclear Physics, including Plasmas, with expertise on the interaction of radiation with materials. Salary scales: 1977/78—Senior Lecturer TT\$25,827 to TT\$34,017 p.a.; Lecturer TT\$19,071 to TT\$29,799 p.a. (£1 sterling=TT\$4.62) F.S.S.U.: Unfurnished accommodation if available at 10% or furnished at 12% or housing allowance of 20% of pensionable salary. Family passages. Study and Travel grant. Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Secretary, U.W.I., St Augustine, Trinidad as soon as possible. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90-91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. 7009(A)

At Last! A Reliable Incubator Under \$100 Designed for Aerobic or Anaerobic Tissue Culture Experiments

Shown at ASM and
FASEB Meetings

Dealer inquiries invited

With this Modular Incubator Chamber you no longer have to worry about the inherent variability (due to CO₂, temperature and humidity fluctuations) of present day continuous flow and anaerobic incubators. Simply place your experiment into the sealed chamber, purge the system with the required gas mixture and set in a controlled temperature environment.

Because each chamber is an isolated system you now have the flexibility to design experiments you previously thought were impractical or too expensive.

Chamber and tray components are made from rugged, non-toxic, uv-resistant polycarbonate.

Multi-purpose trays conveniently hold petri dishes, test tubes, T.C. flasks, microtest plates, etc.

Chambers can be stacked and interlocked for agitation or storage.

And now for the best part. The price of the chamber with 3 trays is only \$95*. To order or for further information phone or write Billups-Rothenberg, Inc., Dept. N-1, P.O. Box 977, Del Mar, CA 92014 USA (714) 755-3309.

To Each His Own

BOC-ON Di-tert-butyl Dicarbonate

The *tert*-butoxycarbonyl (*t*-BOC) group is one of the most important amino-protecting groups in peptide synthesis.¹ For a long time Aldrich offered *tert*-butoxycarbonyl azide (*t*-BOC azide), a useful reagent for the preparation of valuable *t*-BOC-protected intermediates, until it was withdrawn from our listings because of reports of its thermal instability and shock sensitivity. We are pleased to replace *t*-BOC azide with **BOC-ON** [2-(*tert*-butoxycarbonyloxyimino)-2-phenylacetonitrile] and **di-*tert*-butyl dicarbonate** (di-*tert*-butyl pyrocarbonate). Both of these reagents react

BOC-ON

Di-*tert*-butyl dicarbonate

simply and rapidly with amino acids to provide the protected derivatives in excellent yields.

tert-Butoxycarbonylation with **BOC-ON**^{2,3} is accomplished by stirring a dioxane solution of the amino acid with a 10% excess of the reagent and a 50%

excess of triethylamine at room temperature for several hours. Several *t*-BOC-amino acids prepared in this manner are given in Table 1.³

Table 1

Amino acid	Yield (%)
Gly	87
Leu	72
Met•DCHA	82
Phe•DCHA	98
Thr•DCHA	100
Tyr•DCHA	82

tert-Butoxycarbonylation with **di-*tert*-butyl dicarbonate**^{4,5,6} involves the treatment of the sodium or amine salts of amino acids with di-*tert*-butyl dicar-

bonate at room temperature for 10-30 minutes. Only *tert*-butyl alcohol and carbon dioxide are formed as by-products.

Some of the *t*-BOC-amino acids which have been prepared in this manner are given in Table 2.⁴

Table 2

Amino acid	Yield (%)
Ala•DCHA	84-88
MeAla	74
Val•DCHA	88
(Lys) ₂ Cu	94
(Orn) ₂ Cu	95
Asp(OBzl)	83
Glu(OBzl)•DCHA	86

Aldrich is pleased to offer a choice between two excellent reagents for the introduction of the *t*-BOC protecting group. To each his own!

Find out why more researchers use S&S membranes for RNA/DNA hybridization, protein binding, DNA sequencing, and DNA blotting.

It won its reputation as B6, its old name. Now its catalog number is BA 85. They're two numbers for the same S&S nitrocellulose 0.45 μ m membranes. Either way, more researchers use S&S 0.45 μ m membranes than any other brand, in circles for adsorption of DNA strands and in sheets to blot DNA fragments from gels. As the laboratory standard, S&S is specified and preferred in most of the papers published on RNA/DNA hybridization, protein binding assays, or RNA or DNA sequencing.

If you don't know why, it's easy to find out. Fill in and mail the coupon to S&S, and receive a free sample of S&S BA 85—a 15cm square or circles up to 50mm diameter.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to e^a if '*a*' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

- only one reference number need be used if the reference is to several papers by identical authors.
- first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely.

Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976).

JOURNAL OF CARDIOVASCULAR PHARMACOLOGY

An international, multidisciplinary journal devoted to furthering the exchange of new information on cardiovascular pharmacology.

Editors-in-Chief:

Jan Koch-Weser and William Pettinger

Published bimonthly beginning January 1979.

Subscription rates: **\$48.00 U.S.A.; \$56.00 Elsewhere.**

RECEPTOR BINDING STUDIES IN ADRENERGIC PHARMACOLOGY

Lewis T. Williams and Robert J. Lefkowitz

This book reviews in detail the recent explosive development of information concerning the molecular properties of the receptors for catecholamines, generally termed alpha- and beta-adrenergic receptors.

166 pages, \$21.45 (1978)

CYCLIC NUCLEOTIDES, PHOSPHORYLATED PROTEINS, AND NEURONAL FUNCTION

(Distinguished Lecture Series of the Society of General Physiologists, Vol. 1)

Paul Greengard

This monograph summarizes what Professor Greengard considers to be some of the major aspects of cyclic nucleotides, phosphorylated proteins, and neuronal function, subjects to which he has made major contributions in recent years, and which are of fundamental importance to cellular regulation in general and neuronal function in particular.

140 pages, \$15.60 (1978)

POLYAMINES AS BIOCHEMICAL MARKERS OF NORMAL AND MALIGNANT GROWTH (Progress in Cancer Research and Therapy, Vol. 8)

D. H. Russell and B. G. M. Durie

This monograph provides clinicians with a treatise which details the role of polyamines as biochemical markers of success and failure in cancer chemotherapy.

198 pages, \$22.75 (1978)

CENTRAL MECHANISMS OF ANORECTIC DRUGS (Monographs of the Mario Negri Institute for Pharmacological Research)

S. Garattini and R. Samanin, editors

This volume surveys the current knowledge of the alterations of the central mechanisms involved in the regulation of food intake by anorectic drugs.

501 pages, \$45.50 (1978)

ADVANCES IN PROSTAGLANDIN AND THROMBOXANE RESEARCH

Series Editors: **Bengt Samuelsson and Rodolfo Paoletti**

Volume 5:

METHODS IN PROSTAGLANDIN RESEARCH

J. C. Frölich, editor

This practical manual describes in full detail methods that have been proven useful in the discovery, identification, and quantitation of prostaglandins, thromboxanes, prostacyclin, and their metabolites.

250 pages, \$31.20 (1978).

Volume 4:

PROSTAGLANDINS AND PERINATAL MEDICINE

Flavio Coceani and Peter M. Olley, editors

This multidisciplinary approach to prostaglandin research in perinatal medicine features reviews of the role of prostaglandins and allied compounds in the fetus and newborn, clinical applications of prostaglandin research, and the impact of recent discoveries of prostaglandin I₂ and thromboxane A₂ on research in the fetus and the adult.

428 pages, \$45.50 (1978)

Volume 3:

PHOSPHOLIPASES AND PROSTAGLANDINS

Claudio Galli, Giovanni Galli, and Giuseppe Porcellati, editors

Contributions from biochemical and pharmacological research focus on the structure and function of phospholipases, their cellular and subcellular localization and activity, and prostaglandin and thromboxane biosynthesis.

224 pages, \$28.60 (1978)

DOPAMINE (Advances in Biochemical Psychopharmacology, Vol. 19)

Peter J. Roberts, Geoffrey N. Woodruff, and Leslie Iverson, editors

This book provides the most up-to-date information on the neurochemistry and pharmacology of dopamine, ranging from molecular mechanisms at the receptor to therapeutic approaches in disorders of brain dopamine metabolism.

429 pages, \$35.75 (1978)

NEUROTRANSMITTER RECEPTOR BINDING

Henry I. Yamamura, S. J. Enna, and Michael J. Kuhar, editors

This text covers, in a clear and concise fashion, the fundamental principles of neurotransmitter receptor binding assays, as well as the methodology and applications for use in neurobiological investigations, drug screening, neurochemical analysis, histochemical studies, and in the solubilization and isolation of receptors.

210 pages, \$22.10 (1978)

14 September 1978

Why go to the British Association?

IN many ways the annual meeting of the British Association for the Advancement of Science, just concluded in Bath, was quite a success. There was an excellent turnout of members of the young scientists' wing of the organisation—several hundred students in the 11-to-18-year-old category were regular attenders at the meeting and seemed both to enjoy themselves and learn a lot. Audiences were supplemented by the usual senior contingent of enthusiasts for science, some with a professional interest in science, others keen amateurs. A wide variety of lectures was available, including, as is customary, sections on geography, sociology and economics. Symposia on broad topics such as national food requirements, science and technology for development and decision-making in science drew reasonably good crowds. The only thing missing was a reasonable turnout of the research scientists—academic, industrial and governmental—whose work the association attempts to portray.

Certainly there were nearly three hundred speakers in the four days of the meeting, and most of these were actual researchers themselves. But many of these stayed long enough to deliver their wares and no longer. The number of those actively involved in research (outside the officers of the sections) who gave the meeting four, three or even two days of their time was exceedingly small.

There are some very sound reasons for this: the meeting comes in the midst of university vacations; there are other more specialised conferences that have to be attended; there is a limit to the number of conferences any one scientist can be expected to attend, and (a circular and slightly less sound argument) there are not enough like-minded people around to warrant staying any length of time.

Of course the meeting is not a high-powered affair and there is no obvious immediate research benefit

from attendance, but are the channels by which scientist can speak to scientist across the disciplines so good elsewhere that the British Association can be ignored? For one of the most widely remarked features of science is that significant advances frequently occur when people from one discipline discover intellectual sustenance in another, maybe remote discipline. The chance to make new contacts over a period of a few days seems just the sort of 'removal of those disadvantages that impede scientific progress' which the founders of the association aimed at.

But there is another more selfless reason why research workers should attend the annual meeting more consistently—the good effect they can have on the enthusiastic young contingent. Whilst it is not necessary that every lecture delivered to the association be comprehensible to a 16-year-old, many of these young scientists would value relaxed conversations with people whom they obviously respect. Such conversations would help them understand just what it is like to be a scientist and which particular fields of study might appeal to them. The profession of research scientist is not easily understood from outside and is subject to many misapprehensions; evenings of chat in coffee bars are probably as good a way as any of dispelling illusions and clarifying ambitions.

If there was one other disappointment in the attendance at Bath it was the poor, almost negligible turnout of those who are involved in big decisions which can have a scientific content. One would have thought that many politicians, top civil servants and leading industrialists would use such an occasion to keep well informed and to sound out their constituencies. Not so. This is done in comparable assemblies in some other countries, but not in Britain. The result is a narrow-mindedness and compartmentalisation that seems particularly severe in British public life.

A. J. V. Gale 1895-1978

ARTHUR GALE, joint Editor of *Nature* from 1939 to 1961 and associated with the journal since 1920, died on 4 September 1978.

Educated at Selwyn College Cambridge, he was involved in military service for most of the First World War, and was then persuaded by Sir Richard Gregory, recently appointed Editor, to join *Nature* as Assistant Editor. In 1939, on Gregory's retirement, the editorship passed into the joint hands of Mr Gale and Mr L. J. F. Brimble, who had come to *Nature* in 1931. Brimble continued after Gale's retirement to edit the journal single-handed until his death in 1965.

In order that Gregory and later Brimble should lead a lively public life, attending conferences, meeting scientists, championing causes, it was necessary that someone of scrupulous habits should be back in the

office ensuring that the journal appeared on time each week, and that the appropriate bread and butter of *Nature* was attended to. This Gale did to perfection. He knew exactly what *Nature* was about, and he understood the science well, but his responsibility was not to comment or interpret but to ensure that other people were free to do so. He was essentially the servant of *Nature* and thereby of the whole scientific community.

He claimed that he only ever wrote two leaders, yet paradoxically they were at a most momentous time for science's relation with society: the two weeks following Hiroshima and Nagasaki. His calm and sensible words at that time made one regret that he did not write more often.

He married Gwendoline Veysey in 1929 and to her and to his son and daughter we send our sympathy.

Biologists urge US endowment for conservation

One in five animal species may be extinct by the year 2000, writes **John Douglas**

AMID dire predictions about the future of tropical forests and endangered species, an international group of biologists has called on the United States government to establish a national endowment, similar to the national endowment for the arts, "to support original research, both theoretical and applied, in the area of conservation biology". The conference also called on governments and private groups of all developed nations to offer their support to establish and protect "some remnants of natural habitat in tropical countries". Both resolutions were adopted by acclamation at the end of a four-day conference on conservation biology at the University of California, San Diego, last week.

In recommending establishment of the new research endowment, the conference members cited the present lack of any appropriate US agency to fund and coordinate research in environmental management, wildlife biology and conservation. "In particular, we need an agency to fund research relevant to the stewardship of the Earth's remaining natural diversity". Specifically, the resolution calls for increased support for breeding programmes to help save endangered species, research on the ecology of endangered habitats, and an inter-disciplinary approach to the biology of conservation, environment, and animal populations.

To help preserve remaining tropical habitats, the conference again called on the US government to take the lead by launching a major programme "to aid underdeveloped nations financially in establishing and protecting national parks and biological reserves". Otherwise, the resolution concluded, destruction of tropical forests may seriously affect climatic stability, soil erosion, water quality and economic development, "generally impoverishing human existence".

The plight of tropical forests was detailed in a paper by T. C. Whitmore of the University of Oxford. "The second half of the 20th century will stand in history as the brief period during which man reduced the area of the world's richest and most complex ecosystems to about one-third of their potential area", he said. "An onslaught has developed on tropical moist forests which is predicted to continue to accelerate to reduce them to scattered fragments by 2000 AD."

Between now and the turn of the century, the demand for tropical hardwood log production is expected to triple, said Dr Whitmore. That will

require cutting 556 million hectares of forest, leaving only 30% (480 million hectares) of the total area under virgin conditions. Furthermore, the process of using bulldozers to retrieve the logs may compact as much as 70% of the soil in affected areas, hindering forest regeneration. "The prospect is frightening" he concluded.

Even if large national parks and game preserves are established, however, the loss of the great tropical forests will halt the further evolution of most tropical vertebrate species and drive many animals into extinction, according to papers delivered by Michael Soule and Bruce Wilcox of the University of California, San Diego. By using species data from island habitats the authors estimated the minimum area required for various animals to continue speciation. Even the largest of today's national parks are too small by an order of magnitude to foster continued evolution of large mammals, they conclude.

As a result of inbreeding and environmental accidents, Soule and Wilcox predict that the animals trapped in reserves too small for their continued evolution will begin to die out. Taking 19 East African national parks

as an example, the researchers conclude that 11% of the large animal species will have become extinct in 50 years and 44% will be gone in 500 years, unless new management techniques are introduced. If present trends persist worldwide, only about 1% of the Earth's surface will remain in a preserved condition by the turn of the century, which would eventually lead to the extinction of perhaps 3.5 million of the known 5.0 million terrestrial animal species. One million may disappear just by the year 2000. "The ark is sinking" says Wilcox.

Several speakers addressed the question of how large a population of animals must be in order to avoid eventual extinction, and what breeding practices might be adopted to encourage the vitality of a species. Ian R. Franklin of the Genetics Research Laboratories (CSIRO), North Ryde, New South Wales, estimated that genetic considerations alone would require an "effective population" of at least 500 individuals. (Since not all members of a group of animals contribute equally to the gene pool of the next generation, the number of genetically "effective" individuals ranges between roughly half and three-quarters of the total population.) Below the minimum population, Franklin says, the random loss of desirable traits,

Animal behaviour

KENNETH MELLANBY

I WAS recently a member of a panel on a radio programme which discussed the topic "Do animals have rights?" The panel included representatives of animal protection societies and a scientist involved in research. The scientist was a well-known journalist and broadcaster. We had a live audience of about 200 and

the programme, with short breaks for advertisements, went on for an hour and a half.

The programme started with the chairperson asking the members of the panel to state, briefly, their views on animal's rights. All agreed that animals should not be made to suffer unnecessarily, but disagreed as to what suffering meant, and on obvious subjects like vivisection, hunting and factory farming. I thought that we should concentrate on man's responsibilities rather than on animal's rights. Domestic animals, cattle and sheep, and pets such as dogs and cats only exist because man breeds them, and controls the numbers which are born. Without man, most breeds would soon become extinct, though in some areas cats have escaped and become pests, endangering the native fauna. As man has created domestic animals, he has the responsibility for providing conditions where they do not suffer—even conditions where we can reasonably imagine that they enjoy life. But if man disappeared from the world, so would most domestic animals.

The situation regarding wildlife is different. Wild animals, for the most

Left: trans-Amaçonia highway and the jungle; right: maned lions each worth half-a-million dollars as Kenyan tourist attractions

called "genetic drift" will make a species unfit for survival.

Much of the problem of establishing and maintaining large reserves is economic: the need is greatest in areas encompassed by the world's poorest nations. William G. Conway of the New York Zoological Society concludes "The preservation of the majority of the animals that man finds attractive probably cannot be sustained on any provable economic basis". However, some nations, he says, have successfully used their preserves to bring in hard currency through tourism. In Kenya's Amboseli National Park, for example, a single maned lion is estimated to be worth \$515,000 as a tourist attraction, compared to only \$1,150 for commercial purposes as a skin.

For those animals that cannot be preserved in the wild, Conway suggests the limited use of zoos as "gene banks"

until future generations can be re-introduced into the wild. With careful mating, the number of individuals needed might be as small as 50 to 100 animals, he says, but even then half their genetic diversity would be lost and only 100 species could thus be maintained if half of all the zoo capacity in the United States were marshalled to the task.

Another way to preserve species by making some of them more profitable to indigenous people was discussed by Malcolm Coe of Oxford. The oryx, for example, is better adapted to life in Africa than cattle, he said, and some domesticated herds of eland, springbuck and greater Kudu have been established. Another advantage of using such wild ungulates for food comes from their high proportion of lean meat — 43% compared to 23% of the carcass of cattle raised under the same

conditions. Even crocodiles might be raised as a valuable cash crop, since their hides bring a high price and they grow much faster in captivity.

The generally sombre message of the conference was phrased in particularly vivid terms by Thomas E. Lovejoy of the World Wildlife Fund. Between 50% and 85% of all species on Earth have yet to be named, he said, and a major fraction of these may pass entirely out of existence still unrecognized. They will be replaced by the quickly evolving, highly productive species that can coexist with man, often as pests. "Cockroaches and Norway rats will loom larger in 21st century bestiaries," says Lovejoy, "as will crabgrass and dandelions in the floras".

Bison trouble

BYELORUSSIA has been facing a somewhat unusual hazard of conservation at the—literally—grass-roots level. The primeval Bielaviezskaja forest is a reserve for, among other species, Europe's last remaining bison. Virtually exterminated during the war, the bison herd is now multiplying in a most satisfactory manner, and it is hoped shortly to remove the bison from the Red Book of endangered species.

In the meantime, however, bison can occasionally cause problems — as certain collective-farmers found this summer. On the "Komintern" collective farm near Barysau, one particular bison claimed as its range a large hayfield, chasing the only farmer who dared approach it up a tall tree.

Denied more "radical means" of evicting it, the Farm Management Board decided to leave the field to the bison — whereupon several other bison moved in. To date no information is forthcoming as to whether the bison have been dislodged.

This is not the first time that forest bison have caused disruption of local life; a few years ago, at Hajdowka on the Polish side of the forest, one of the local bison went to sleep on the railway lines, following this exploit by a visit to the local school.

Vera Rich

part, only continue to exist where man has left conditions—habitats—suitable for them. As a conservationist I think that we should do more to preserve and develop such habitats, even though this conflicts with the needs of agriculture to produce food for the growing human population.

Although the producer of this radio programme had tried to provide a balanced audience, and had invited farmers, those engaged in animal experiments, and sportsmen to participate, these groups were greatly outnumbered by those who considered themselves to be animal lovers. There were colourful and hirsute young men and drab girls wearing T-shirts proclaiming them to be hunt saboteurs. We had anti-vivisectionists of all persuasions, vegetarians, some milk drinkers, some vegans, and some who seemed mainly to wish to oppose the politics of the establishment. Although there were good questions and sensible comments from the floor, the majority of the audience had not come to listen or to discuss. Their purpose was to stop those with whom they disagreed from speaking.

Thus when one panel member tried

to give the correct breakdown of the number of animal experiments in Britain, showing that these were mostly for genuine medical tests and not just to swell the profits of cosmetic manufacturers, a section of the audience, largely consisting of remarkably unattractive women resembling those who knitted when the guillotine functioned in revolutionary France, bayed "Lies, lies, lies, sit down, we won't listen to your lies". When I was asked about the policy of culling red deer in the Scottish Highlands, and said this was necessary to keep the population healthy, as otherwise, as wolves and other predators which controlled numbers were no longer present, the deer would increase until many died from starvation and disease, someone shouted: "Why not cull human beings?" The noise made by the audience was quite alarming, and made the interruptions heard at question time in the British parliament sound almost human.

I am afraid that my main reaction to the evening's entertainment was to wonder why those who profess to love animals hate their own species so much!

Science at the UN: coordination or chaos?

Peter Collins reports on the likely demise of the UN's only scientific advisory body, 'ACAST's. Who will replace it?

AT least we should be represented at our own funeral" remarked the chairman of ACAST's recent meeting in Geneva. For this, the United Nations Advisory Committee on the Application of Science and Technology, is almost certainly one of the bodies likely to disappear in the restructuring to which its parent body, ECOSOC (the Economic and Social Council) is now being submitted. In this process ACAST has no say, and may find few friends to speak up on its behalf: government delegates as a whole, and especially those of the developing countries who hold a voting majority, do not like independent committees. Be that as it may, the abolition of ACAST at the present juncture would be most unfortunate. Its recent meeting was one of the liveliest and most useful since its foundation, and its discussions had an air of realism and urgency often lacking in past. This was perhaps due to the presence of several new members of this individually selected body, invited to replace some of those who had given it the reputation of representing the scientific establishment, with few original ideas and, at times, little apparent awareness of the trends and possibilities of modern science and technology.

In search of harmony

One of the major subjects discussed was the matter of policy for science and technology within the UN system itself. ECOSOC went on record some time ago to the effect that "the planning of activities in the various organisations of the United Nations should be harmonised and gradually integrated into a United Nations science and technology policy".

However, the idea of a centrally-controlled, general policy for science and technology within the system is widely considered to be impracticable, even if indeed it is desirable. What is seen as a reasonable objective is the harmonisation of policies within and between the various parts of the system. Some decisions on this subject are expected to form part of the Programme of Action for UNCSTD next year, and some sort of closer coordination in this field is also seen as essential for the evolution of the "new international economic order", in which the whole UN system and its member governments are now involved.

When it came to the means of bringing about such harmonisation, ACAST considered three main possibilities. The

first of these was creation of a new agency charged with the overall coordination of science and technology for the entire system. ACAST commented that "experience in the United Nations (as well as with almost all organisations) is that new agencies become concerned not only with their own survival but also with increasing their influence and activities."

The second possibility, the suggestion of setting up an organisation for science and technology equivalent to the UN Environment Programme, was looked on somewhat more favourably. But to be effective it would sooner or later require, as has UNEP, a fund, and it is unlikely that member governments would agree to the creation of yet another large fund with all its administrative costs and the need for constant checks on the validity of the operations in which it might become involved. In any event, such a programme would have to rely on inputs from the rest of the system, and would need to have sufficient political or other support "to ensure consistency among the various agencies objectives and strategies through its decisions regarding funding and through coordination".

Much the most attractive, at least under present circumstances, would appear to be the third possibility, defined as a Centre for Concerted Action and Coordination on Science and Technology. Its purpose would be to systemise and synthesise information on all science and technology programmes and strategies throughout the system; to keep the Secretary-General advised of what was going on and what were the objectives and sub-goals of the other organisations within the system, relating these to the overall objectives; and to maintain contacts with the scientific and technical community, including intergovernmental and non-governmental organisations.

Questions involving research could be referred to other organisations within or outside the system, or, suggest ACAST, "to a committee of no more than twelve top-level experts or to such *ad hoc* advisory committees or working groups as might be necessary". Such a centre could create the setting for some sort of planned policy-making for science and technology within the system, besides providing a mechanism for coordination and harmonisation. Because it need have only a small staff, it could be flexible and could respond quickly to changing situations and in

providing advice to the Secretary-General. At the same time, it would compete with no existing organisation for either resources or authority.

If set up at the present juncture, such a centre could be designed to allow for the present restructuring of the various organs involved in ECOSOC and in the central control of the UN itself. Nonetheless, it would still have to face the problem raised by the specialised agencies which still seem set against any form of coordination, let alone integration, as was also made clear at the ACAST meeting.

A message for UNCSTD

From the immediate point of view of the scientific community outside the UN, the most interesting discussions concerned the meeting to be held in Vienna in the week immediately preceding UNCSTD, 13-17 August, 1979. Known hitherto as "Forum A" (to distinguish it from "Forum B", the non-governmental event being held parallel with UNCSTD and organised by the Austrians themselves), this is now the responsibility of ACAST, and will probably be called the "ACAST Colloquium on Science, Technology and Society". It will be confined to some 200 invited scientists, technologists and other persons, including governmental representatives and those of interested organisations outside the system. Provision is being made for science writers and other journalists and possibly, if space allows, for members of the public. This is intended as a serious scientific meeting, the output of which will include a message from the world scientific community to UNCSTD, as well as proposals relevant to the conference programme of action.

Besides various papers to be prepared by the UN Office of Science and Technology, which is providing the secretariat for this meeting, there will be important inputs from four symposia being held within the context of UNCSTD between now and next summer. These include that at Tallin, on Trends and Prospects with regard to the Development of Science and Technology (4-8 December 1978); Science and Technology for Development (Singapore, March 1979) organised by a group headed by ICSU; Technology for Development (Abidjan, Ivory Coast, April 1979); and Science and Technology in Development Planning (Mexico, May 1979).

Priority among subjects discussed at the present ACAST meeting went to those on which the committee's views had been requested by José da Costa, Secretary General of next year's UN Conference on Science and Technology

for Development (UNCSTD). Insofar as the conference itself is concerned, the most important of these was the discussion of "obstacles to the application of science and technology for development". Having as a basis a list of 31 general areas in which such obstacles might arise, ACAST pointed out that this list could be expanded to a hundred or more. It considered them by categories, each of which might be susceptible to the same type of solution at national, regional, or international level. They then fell into two broad groups: political, financial, economic and institutional obstacles to development; and those involving education and human resources, the availability and dissemination of information, and the psychological problems inherent in any society subject to the pressures inseparable from rapid development.

ACAST's suggestions stress the need for an integrated approach to specific problems that are seen as capable of reasonably early solution. Thus, to give a few examples: to improve the communication gap in a given country between its scientific and technological community, decision-makers and users, a well-mandated national advisory council might be set up, that would monitor trends and developments and interpret them to the leadership, as well as interpret political goals and objectives to the scientific and technological community. At the regional level, programmes of common interest could be identified as part of regional economic planning policy, with a regional machinery to coordinate and evaluate their performance. At a practical level, regional servicing facilities might be established, to maintain and service the special equipment of all developing countries in the region; it could maintain a spare parts bank to avoid the harrassment of delays in obtaining equipment spares. With regard to in-

formation at both regional and international levels, there should be a network of information systems not only to act as a data bank, but also to assist in collecting trends of development in technologies and to interpret their implications for developing countries.

ACAST concluded that "at the national, regional as well as international levels, the psychological obstacles can only be removed by redesigning and strengthening the education, training and information systems".

Recognising social science

Finally, ACAST briefly discussed its own future. Obviously, if something like the UN Centre for Concerted Action and Coordination on Science and Technology described above is set up, there would be a function for a small body similar to ACAST, and this is already foreseen in the suggested "committee of top-level experts". One point of which ACAST is now well aware is the need to include, in whatever body replaces it after UNCSTD and as a result of the restructuring exercise, representatives of the social sciences. The intention was never to include these when ACAST was set up in 1964, but their presence is at last seen as essential if a balanced view is to be obtained of what science and technology are doing, can and should be able to do, in the world as a whole. This much is now recognised. But whatever the decisions of the General Assembly, which has the final say in ACAST's future, it is certain that some such body must exist if the UN Secretary-General, essentially preoccupied with political affairs and the infighting of the UN system, is to be kept aware of what is happening in the science and technology on which the world increasingly and inevitably now depends. □

Racial resegregation measured

DESPITE decade-long efforts to integrate schools, increase individual welfare payments and revitalize central cities, the underlying conditions attacked by these programs remain almost unabated, according three reports delivered at last week's meeting of the American Sociological Association in San Francisco.

A new study of school integration and the so-called "white flight" of middle class caucasian families to suburbs from the city centres reestablishes the seriousness of this problem, first treated in a controversial report by James Coleman in 1975. Coleman's treatment was severely criticized at the time for neglecting concurrent demographic changes and not distinguishing between forced and voluntary desegregation.

Now, David J. Armor of the Rand Corporation, Santa Monica, California, has analysed integration statistics by estimating what out-migration of whites would have taken place anyway, taking into account the different birth rates between whites and blacks, and comparing the results of court-ordered busing to voluntary methods of desegregation. He concludes that forced integration accelerates white flight by a factor of from two to four, but that voluntary integration may not accelerate it at all.

He compares specific cases by using a "desegregation index", defined as the average percentage of white students in schools attended by minority students. (If minority students were divided among all American schools completely randomly, each school would have a desegregation index of 70 to 80. The smaller the index, the less integration.)

Armor found that, with the beginning of court-ordered integration, the index for a particular school district usually jumps. In one year, the desegregation index of Pasadena, California, rose from 37 to 53. But over the next seven years, it steadily dropped back to 35, in 1977. By comparison, nearby San Diego started its voluntary busing plan in 1968 with an index of 43. The index rose gradually to 46 and has now slipped back to 44.

During roughly the same period, a variety of programs were introduced to help raise the average income of blacks and other minorities. A report by Robert B. Hill of the National Urban League Research Department shows that again many early gains have been eroded by the "benign neglect" policies of the Nixon and Ford Administrations and the two severe recessions of the early 1970s.

Sunspots and flu: a correlation

SIR,—Seasonality exerts a profound but ill-understood influence on epidemic influenza. North of the tropic of Cancer and south of Capricorn epidemics usually break out in winter when the relevant portion of the globe of the Earth is most distant from the Sun. The purpose of this note is to call attention to a longer-term association of type A influenza with solar activity that has become apparent since human influenza virus was discovered in the epidemic of 1932–33, namely that the periods of world-dominance of successive major subtypes of influenza A virus have synchronised closely with the periodicity of sunspots (see Figure). The two sets of cycles are probably synchronised at least as far back as 1917.

Influenza pandemics have occurred in the twelve months after type A influenza virus has undergone an antigenic shift leading to a new major subtype. The new major variant with altered haemagglutinin (H) and neuraminidase (N) finds the population inadequately protected by influenza caused by its predecessor. The change has enabled it to bypass their immunity. The predecessor promptly disappears and the new major variant with its minor varieties dominates the world causing all the type A influenza for the next decade or so until itself displaced by the next antigenic shift. The major subtypes since 1933 have been identified serially according to H & N composition as H_0N_1 viruses isolated before 1947, H_1N_1 1947–1957, H_2N_2 1957–1968, H_3N_2 1968–1978. Each major subtype completely disappeared at the next antigenic shift except that H_1N_1 viruses reappeared in many parts of the world in 1977 and are still (28 July 1978) causing influenza concurrently with H_3N_2 viruses. The pandemic of 1918 is usually attributed to antigenic shift producing the major subtype HSw_1N_1 . A small outbreak caused by virus of this major subtype occurred in 1966.

Sunspots undergo cycles of activity varying from seven to seventeen years,

average eleven years. Activity increases to maximum more rapidly than it declines to minimum, and maxima sometimes stand upon a plateau of several years of approximately equal activity. The true solar sunspot cycle consists of two consecutive cycles of minimum to minimum activity (see Gibson, Edward G. *Rev. Geophys. Space Phys.* 10, 395–462; 1972). Antigenic shifts of influenza A virus to H_1N_1 , H_2N_2 and H_3N_2 coincided with sunspot maxima of 1947, 1957 and 1968 respectively. The sunspot maximum of 1937 coincided with severe and widespread influenza, but no antigenic shift was recorded. The sunspot maximum of 1928 coincided with a pandemic which may have signalled the antigenic shift from HSw_1N_1 to H_0N_1 virus. The previous sunspot maximum of 1917 anticipated the pandemic of 1918–19. Fascinating as it is to attempt to investigate the association throughout the centuries of sunspot records, influenza records are probably too dubious to make the attempt worthwhile. The next sunspot maximum is however to be expected shortly, perhaps in 1979. The behaviour of type A influenza virus during the next few seasons will be watched with keen interest tinged with apprehension.

The Beacon containing an interview in the form of questions and answers between someone described as a *Beacon* reporter and someone *The Beacon* describes as Professor Eysenck. Could the granting of this interview, by one who gives so many, have slipped his mind?

However, the most serious problem with the answers to my letter (*Nature* 274, 738; 1978) is that both Professors Eysenck and Jensen fall yet again into the typological trap of the confusion of social and biological categories. To speak of "racial mean differences" to is do the reverse of to "treat each person individually", which Professor Eysenck claims he wants; it is to categorise them as belonging to a group, which although socially defined (eg, Black, Jewish) Professors Eysenck and Jensen regard as having biological meaning. The resulting scientific errors which flow from their attempts to biometrise group characteristics are apparent to most biologists. As the National Front propaganda has shown, racist ideology feeds on this biologising thinking, and it needs firm public rebuttal.

Yours faithfully,

STEVEN ROSE

Milton Keynes, UK

Racism

SIR,—Professor Eysenck's clear dissociation from the National Front and other 'explicitly' racist organisations is to be welcomed, and I assume that he will be taking steps to ensure that the organisation and its associated journals cease using his name. In the meantime, although I am sure that when he denies that he has given an interview to *The Beacon* he does so in good faith, a further clarification seems required, as I have in my possession a xerox copy of an issue of

Origins of "ecology"

SIR,—In reviewing the book by D. Worster, *Nature's Economy*, Kenneth Mellanby (*Nature*, 6 April 1978) states that Haeckel "is believed to have coined the word [ecology] in 1873". I do not know if the word was used earlier, but it is certainly true that Ernst Haeckel in his volume, *Generelle Morphologie der Organismen*, Berlin, 1866, Vol. 2 ("Allgemeine Entwicklungsgeschichte der Organismen"), p 286, states: "Unter Oecologie verstehen wir die gesamte Wissenschaft von den Beziehungen des Organismus zur umgebenden Aussenwelt". He therefore gives the correct definition of ecology, as we understand it today. Haeckel goes on (p 287): "Dagegen hat sie die Beziehungen desselben zur Aussenwelt, die Stellung, welche jeder Organismus im Naturhaushalt, in der Oeconomie des Natur-Ganzen einnimmt, in hohem Grade vernachlässigt".

Haeckel's definition of ecology, integrated with the concept of ecology as the study of the "economy of nature", is repeated in Haeckel's popular collections of lectures, *Natürliche Schöpfungsgeschichte* (1868), and *Anthropogenie* (1874). Both books were translated into many languages, and had dozens of editions, containing increasing numbers of 'lectures'. Readers may like to refer to a short history of the concepts of 'ecology' and of the 'economy of nature' in my paper: "Ecologia e economia", *Giornale degli Economisti*, 32, 435–455 (1973).

Yours faithfully,

Mussel watching

from B. L. Bayne

BIVALVE molluscs, particularly mussels and oysters, are valuable indicators of pollution in coastal marine environments and estuaries. Among their qualifications for this role are their sessile mode of life as adults and a capacity for accumulating contaminants in their tissues to levels considerably higher than in seawater. The first attribute makes escape from various environmental stresses impossible. The second makes bivalves attractive to analytical chemists; whereas most pollutants may be present in seawater in concentrations between 10^{-11} and 10^{-12} g g⁻¹, concentrations in bivalve tissue may vary between 10^{-8} and 10^{-4} g g⁻¹. Mussels of the genus *Mytilus* fit this role of indicator organism particularly well because they provide convenient amounts of tissue for analysis and because they are common members of benthic (often intertidal) communities on hard substrata, with a wide and circumpolar distribution in boreal and temperate waters of both northern and southern hemispheres.

In 1975 Ed Goldberg, of the Scripps Institution of Oceanography, proposed a 'mussel watch' in which collections from many sites would be analysed regularly for their body-burdens of heavy metals, halogenated hydrocarbons, petroleum hydrocarbons and transuranic nuclides. The results would provide "a continuing revelation of how man's activities are altering oceanic composition" (*Mar. Poll. Bull.* 6, 111; 1975). In 1976 this idea bore fruit with a surveillance programme in the USA, under contract with the US Environmental Protection Agency. Samples of mussels or oysters are taken from 107 stations on the West, Gulf and East coasts of the US and analysed in five laboratories, each main class of contaminant being treated independently by two analytical groups. The results of the first year's work have now been published by Goldberg *et al.** The report

includes a discussion of sampling strategies, of some of the problems associated with seasonal and size variability, and of the economics involved in sampling and analysis, as well as providing detailed tables and discussions of the results.

In projects of this kind care is needed in designing the sampling procedure in order to ensure true compatibility between sites. Ideally, animals should be taken at a standard size, since the accumulation of metals at least, is known to be size dependent (Boyden *J. mar. biol. Ass. U.K.* 57, 675; 1977). Sampling should be limited also to a standard tidal level on the shore and to a particular season of the year (Phillips *Environ. Pollut.* 13, 281; 1977). When the project covers a very wide geographical area, these may be difficult constraints to meet. Goldberg *et al.* sampled monthly at two stations and found no significant seasonal trend in concentrations of heavy metals or halogenated hydrocarbons; although a seasonal change in ^{239,240}Pu and ²⁴¹Am was interpreted as due to a change in the environment rather than a seasonality in the physiology of the animals. There have, however, been other reports of seasonal changes in the contamination of mussel tissue, a result to be expected knowing the large seasonal changes in metabolism that occur in bivalves associated with gametogenesis and the availability of food. In a widely based mussel watch it would be wisest to include independent checks for possible seasonal effects.

Another problem is posed by the treatment of the samples before analysis. Mussels feed on suspended particulate material (Goldberg *et al.* suggest that this is the main route for contamination by radionuclides) and, particularly in estuaries, their stomachs are likely to contain much inorganic material that would normally be passed out in the faeces. Consequently, a period of 12-48 h spent in clean seawater between sampling and analysis, in order to clear the gut by defaecation, is generally to be recommended.

But this is not practicable in a project on the scale of the US mussel watch, where samples were frozen on dry ice immediately following collection.

Another potential problem, that of calibration between laboratories, was specifically addressed in the US mussel watch, and the results are generally encouraging. Agreement between analytical laboratories was satisfactory for most of the metals and for the transuranic nuclides. Consistent differences occurred between laboratories in the analysis of the two principal degradation products of DDT, p,p'-DDE and p,p'-DDD. These differences are not viewed as alarming, particularly since all samples were sent for analysis to each laboratory chosen to analyse the particular contaminant. However, the need for careful intercalibration studies in future programmes is emphasised.

Having measured the concentration of each contaminant in all samples, a decision on whether the environment is 'polluted' must be made. It is on this point that some argument is to be expected. Goldberg *et al.* recommend that order of magnitude differences (or variations over time) should be considered significant when considering metals or halogenated hydrocarbons. On this basis particular pollution 'hot-spots' are recognised, for example the New York-New Haven area for metals and numerous sites of PCB pollution on the East coast. For PCB 1245, relatively unpolluted areas show tissue levels less than 50×10^{-6} g g⁻¹ dry weight, whereas polluted areas have levels as high as 600×10^{-6} – 800×10^{-6} g g⁻¹. This criterion of an order of magnitude difference in order to discriminate between polluted and unpolluted sites is conservative, but rigorous enough in the context of the US mussel watch data; how generally applicable it may be remains to be seen. In setting such a criterion, however, the need for samples from a large number of sites is emphasised. As Gold-

B. L. Bayne is at the Institute for Marine Environmental Research, Plymouth.

*Goldberg, E. W., Bowen, U. T., Farrington, J. W., Harvey, G., Marth, J. H., Parker, P. L., Risenbrough, K. W., Robertson, W., Schneider, E. & Gamble E. *The Mussel Watch, Environ. Conser.* 5, 1-25 (1978).

berg *et al.* point out, some locally high values for metals, in particular, may be due to natural estuarine run-off (see Bryan & Hummerstone *J. mar. biol. Ass. U.K.* **58**, 401; 1978) rather than industrial pollution. This is one aspect of the perennial problem in pollution monitoring, the setting of natural 'base-lines' for particular contaminants. Only by treating many samples from a large number of sites can a real appreciation be gained of true minimal concentrations of pollutants, and this must be particularly true in the coastal waters of industrialised states.

Using these and other criteria, the US mussel watch has identified certain areas of pollution; some of these conclusions came as no surprise, others remain more of a mystery. The study demonstrates the usefulness of the concept and argues strongly for an even wider geographical coverage. Indeed, Goldberg's original aim was for a global marine monitoring programme. The interest already shown by some countries (the proposed Mediterranean mussel watch, for example) suggests that an increase in geographical scope can be achieved.

This prospect poses a challenge for the biologist. Measuring the levels of

contaminants in the tissues of molluscs does provide information on levels of contamination of the water, but the question naturally follows: "What is the biological impact of these pollution loads?" To some extent, chemical studies of pollution require biological confirmation, for it is in the intensity of the effect on the biota that questions of pollution acquire environmental realism. Means of assessing the biological effects of pollutants are gradually being made available (*On the feasibility of effects monitoring, Co-operative Research Report No. 75*, ICES; 1978) and they vary from measures of biochemical response through indices for assessing the physiological condition of individuals to attempts to relate components of animals' responses to the possibilities of lasting ecological damage. Much of this research is focused on marine bivalve molluscs for the same reasons that render these animals attractive to analytical chemists. In promoting a wider application of the mussel watch concept, therefore, attention should be given to the incorporation of measures of biological impact. Goldberg *et al.* comment briefly on this point in their article, but it is a challenge to which the biologists need to respond. □

Large-scale population studies have clearly shown that a disproportionate number of individuals with particular HLA alleles develop certain diseases. Putative disease-susceptibility genes are spread all along the HLA complex, but the closest associations are with alleles at the D locus. For example, Dw2 is increased in multiple sclerosis, and Dw3 in a number of different autoimmune diseases, including thyrotoxicosis (Graves' disease), spontaneous adrenal insufficiency (Addison's disease), and pernicious anaemia. These same diseases show a significant but somewhat reduced association with one of the antigens in the B series, B8. This finding is most easily explained by assuming that B8 and Dw3 do not sort randomly; that is, are in linkage disequilibrium. As I. Roitt (Middlesex Hospital, London) pointed out, rheumatoid arthritis is unusual in that it associates with Dw-4 and shows no significant affinity for antigens of the A, B, or C series. Although statistically significant, these HLA associations are still distant enough to indicate that other genes and non-genetic factors greatly influence the development of autoimmunity. For example, genetic disorders in the particular target organ or sex-associated factors (these diseases are almost all more common in females than in males) are probably involved.

Sometimes HLA typing helps to distinguish different varieties of what was thought to be the same disease. Two different forms of diabetes mellitus can now be distinguished by HLA typing. The so-called juvenile-onset or insulin-dependent form of diabetes is associated in Dw-3, while individuals without this genetic marker are more likely to develop a late onset form of disease that can be controlled by diet or oral hypoglycemic agents, not requiring insulin. As J. Irvine (University of Edinburgh) emphasised, distinction between the two forms of diabetes should now be made, not on the basis of age of onset, but on HLA type and immunological response to pancreatic islet cells. HLA typing is also useful in prognosis; for example, those patients with Graves' disease who are HLA-B8 are less likely to undergo spontaneous remission than patients lacking this trait. I. Mackay (Hall Institute, Melbourne) distinguished two forms of chronic active hepatitis on the basis of immunological response. The autoimmune type of the disease shows an increase in HLA-A1, B8 and Dw-3. No such HLA association is found in chronic active hepatitis patients who are positive for Australia antigen.

Autoimmunity revisited

from Noel R. Rose

It is now some 25 years since autoimmunity emerged as a plausible cause of a number of mysterious human diseases. But, despite the demonstration of autoantibodies in patients' sera or localised in affected tissues, there has been little understanding of how the autoimmune process gets started. The initiating event in human disease is certainly not deliberate injection of autologous antigen mixed with a suitable potentiating agent like complete Freund adjuvant, as it is in experimentally immunised animals. It now seems likely that one of the important prerequisites of autoimmune disorders in the human is genetic predisposition.

Early evidence that genetic abnormalities predispose to human autoimmune diseases stemmed mainly from two kinds of studies. Astute clinicians noticed that certain autoimmune diseases cluster with unexpected frequency in some families. When objective markers of autoimmune disturbance became available in the form of tests for autoantibodies, a statistically significant increase in auto-

immunity was documented even in clinically unaffected relatives of autoimmune patients. A recent line of evidence to support a genetic predisposition towards autoimmunity has come from investigations relating autoimmune diseases (as well as quite a number of non-immunological diseases) to genetically determined cell surface markers, especially HLA alleles. While rarely firm enough to be of practical diagnostic value, these statistical associations point to the existence of disease-susceptibility genes.

The World Health Organization Collaborating Center for Autoimmune Diseases, located at Wayne State University, sponsored a Workshop on Genetic Control of Autoimmune Disease in July 1978.* The purpose of the meeting was to see if the newly generated information derived from genetic investigations might open novel approaches to the diagnosis and treatment of human autoimmune disorders.

To begin, P. Terasaki (University of California, Los Angeles) and A. Svejgaard (State University Hospital of Copenhagen) analysed the voluminous evidence associating autoimmune disorders with particular HLA alleles.

*The meeting was organised by N. Rose, P. Bigazzi and N. Warner. The full proceedings are being published by Elsevier-North Holland.

Noel R. Rose is Professor and Chairman in the Department of Immunology and Medicine, Wayne State University.

The most likely role of HLA in determining susceptibility to disease is through immune response genes that determine recognition of a particular antigenic determinant. Evidence for this concept is based mostly on the close resemblance of HLA to mouse H-2, which is known to control immune responses.

Among the models available for the study of spontaneously appearing autoimmunity in animals, the New Zealand (NZ) strains of mice have been by far the most profitable. The NZB strain spontaneously develops haemolytic anaemia, and the hybrid obtained by crossing NZB with the apparently normal NZW strain results in an autoimmune disease closely resembling human systemic lupus erythematosus (SLE). Extensive efforts have been made to sort out the several genetic factors controlling these autoimmune disorders, but a clear definition has not yet been obtained. To complicate matters, NZ mice contain abundant type C virus particles. Viral genes code for glycoprotein which closely resembles a mouse glycoprotein, and the possibility was raised that antibody originally induced to viral proteins may cross react with the comparable mouse antigen. However, S. Datta (Tufts University) showed that viral genes segregate independently of 'autoimmunity' genes, removing the possibility of a cause-and-effect relationship between viral infection and autoimmunity.

A more likely possibility to explain the spontaneous development of autoimmune disease in NZ mice is a fundamental disorder in immunological regulation. H. Cantor (Harvard Medical School) demonstrated an early deficiency in the subset of T lymphocytes responsible for immunological equilibrium. These cells, recognised by their antigenic surface markers, Ly 123⁺, produce feedback suppression of antibody production. N. Talal (University of California, San Francisco) further showed that the paucity of suppressor T cells in NZ mice can be at least partially remedied by thymic extracts. Another view of the fundamental NZ abnormality emerged from experiments of H. Morse and T. Chused (National Institutes of Health). B cells of NZB mice show spontaneous polyclonal activation even in the absence of T cells. These findings suggest that NZ mice suffer from an intrinsic lesion in their B cells. There may be a more basic stem cell defect affecting both regulatory T cells and B cells.

In contrast to the multiple autoimmunities present in NZ mice, a single autoimmune disorder can be demonstrated in the OS strain of chickens. These animals spontaneously develop a classical form of chronic thyroiditis. L. Bacon (Wayne State University)

DNA structure and transcription

from Andrew Travers

THE mechanisms controlling transcription during the development of different bacteriophages are extremely diverse. Yet another solution has emerged from the studies of Rothman-Denes and her colleagues on coliphage N4. N4, in common with *Bacillus subtilis* phage PBS2, but unlike all other commonly studied phages, does not apparently require the host RNA polymerase for any viral transcription. Instead the virus contains a virus-coded transcriptase of novel structure. This enzyme consists of a single protein chain about 4,000 amino acids long and is thus one of the largest polypeptides so far identified.

How does this enzyme function? Its equally novel template requirements are now reported in the latest paper from Chicago (Falco *et al.* *Proc. natn. Acad. Sci. U.S.A.* 75, 3220; 1978). *In vitro* N4 RNA polymerase strongly prefers N4 DNA, which it copies asymmetrically, producing transcripts corresponding to those RNA molecules synthesised *in vivo* immediately after phage infection. However, in contrast to other bacteriophages, the enzyme has the virtually absolute requirement that this template be denatured. Another pointer to the unusual nature of the specificity of the enzyme is the observation that *in vivo* N4 RNA synthesis is specifically inhibited by coumermycin, a drug whose target is DNA gyrase, the enzyme responsible for inserting negative superhelical turns into closed circular duplex DNA. These results suggest that DNA gyrase must modify the structure of N4 DNA before it can be transcribed by the virion RNA polymerase. Consequently, the authors propose that superhelical DNA may be the required natural template for the enzyme.

Assuming this hypothesis to be correct, we have to ask how the introduction of negative twists into presumably closed circular N4 DNA

so dramatically promotes transcription. The best current analogy comes from studies on *Escherichia coli* RNA polymerase. Before initiating transcription this enzyme recognises a promoter site extending over a region of at least 40–50 base pairs, and subsequently effects a change in DNA conformation at the binding site, a process termed promoter opening. It is well established that increasing the superhelical density of phage DNA templates substantially enhances the rate of transcription initiation by the bacterial polymerase. This enhancement could result from a direct facilitation of enzyme-mediated promoter opening. Alternatively the introduction of superhelical turns could alter the parameters which the enzyme recognises in the DNA template sufficiently to change the initial affinity of the polymerase for a promoter site.

At present the available experimental evidence does not distinguish between these possibilities. However, Levitt (*Proc. natn. Acad. Sci. U.S.A.* 75, 640; 1978) has recently calculated that supercoiling can, in theory, alter the number of base pairs per turn of the double helix by as much as 5%. If this result is applicable to the real world, it is difficult to escape the implication that the spatial arrangement of the DNA sequence in a supercoiled molecule differs substantially from that in a relaxed one. Consequently unless one invokes the additional *ad hoc* assumption that RNA polymerase possesses a similar molecular flexibility it seems highly plausible that the detail of the initial contacts of the enzyme with a given promoter site will strongly depend on the extent of superhelicity of the template. However, the capacity of the bacterial polymerase for differential promoter recognition can be extensively modulated by factors other than subtle variations in DNA structure. Under these circumstances the N4 virion RNA polymerase promises to provide an attractive simpler system to test for the effects of supercoiling on promoter recognition and opening.

Andrew Travers is at the MRC Laboratory for Molecular Biology, Cambridge.

found that the trait is polygenic but is significantly linked to the B locus (the chicken's MHC) in certain families. In other families the B locus linkage may be obscured due to over-riding effects of other genes. Other genetic defects have been found in the OS thymus and in the thyroid gland itself.

On the basis of the many studies of spontaneously developing autoimmune disease in animals, three types of genetic eccentricity can be recognised. One is an increase in immunological responsiveness, possibly due to the presence of immune response genes within the MHC. Such a

gene is probably present in the OS chickens. A second lesion appears in the thymus and in the regulatory cells developed in the thymus. A third genetic defect probably occurs at the level of the target organ and determines where the particular pathological damage may be found.

Among the models of induced autoimmunity in animals, the most clearly defined is experimental allergic encephalomyelitis (EAE). D. Gasser (University of Pennsylvania) found that in the rat the development of disease is associated with the MHC, but other non-MHC related genetic controls can also be recognised. In mice the situation is even less clear-cut, because natural suppressor cells have a major, and possibly over-riding, influence. In some strains it is possible to detect genetic control by reducing the effect of T suppressor cells with cyclophosphamide treatment (R. Arnon, Weizmann Institute).

Another good model for studying genetic control of induced autoimmune responses is experimental thyroiditis. In mice, where many genetically defined inbred strains are available, Y. Kong (Wayne State University) was able to delineate at least two genes that regulated the response to mouse thyroglobulin. One, located near the K end of the H-2 complex, appeared to be a typical immune response gene. A second-order gene near the D end of the complex modified the immune response so that the pathological damage to the thyroid was heightened or diminished.

H. Wekerle (Max Planck Institute, Freiburg) has developed a method of autosensitising T lymphocytes *in vitro*. His experiments strongly suggest that self-responsive precursor T cells are normally present in the body but held in check by homeostatic immunological mechanisms. Further evidence that self-responsive lymphocytes are normally present to testicular antigens emerged from experiments described by P. Bigazzi (University of Connecticut), who found that vasectomy of rats and mice engenders production of sperm-specific antibody, a response also reported in vasectomised men.

Until recently, most immunologists believed that the lack of response to self-antigens came about because lymphocyte clones that carried receptors to self-antigens were eliminated at birth. The investigations described during the Cranbrook meeting contradicted this view. The data showed that both T cells and B cells capable of reacting with many self-antigens are present and waiting to be triggered. The prevention of autoimmune responses, therefore, requires continuous and active suppression.

Two regulatory mechanisms were

discussed in some depth. The first is the generation of antibodies to idiotypes, as described by H. Wigzell (University of Uppsala). Idiotype determinants characterise antibody molecules and immunocompetent cells of a particular antigenic specificity. Idiotype antibodies are strong candidates for physiological regulators of immune response, as they can control production of antibodies with particular specificities by stimulating or inhibiting idiotype-bearing immunocompetent cells.

Immunological regulation also depends on the balance of suppressive and stimulatory subsets of T cells. The balance depends on the properties of the antigen and the method of administration. R. Swanborg (Wayne State University) found that certain determinants of the EAE antigen favour suppressor cell production, specially if given with incomplete rather than complete Freund's adjuvant. E. Engleman (Stanford University) reported that he could generate *in vitro* a factor from human T cells that suppressed allogeneic lymphocyte interactions. The suppression is genetically

restricted by the D locus of the reacting cells, re-emphasising the crucial role of the MHC in immunological regulation.

To many participants, the meeting at Cranbrook foreshadowed a new stage in the thinking about human autoimmune disease, with a shift from descriptive to interventionist approaches. Until now, genetics has contributed mainly to understanding the natural history of autoimmune disorders, offering improvement in diagnosis and classification. Now it seems that the tools may be at hand to arrest the pathological process. One most promising lead is the deliberate generation of suppressor T cells *in vitro*, possibly followed by hybridisation with established cell lines and production of suppressor factors. Another possibility is to induce idiotype antibodies with restricted specificity for self-reactive immunocompetent cells. The coming years should provide several opportunities for designing specific immunotherapeutic manoeuvres rather than relying on nonspecific immunosuppression for the treatment of autoimmune diseases. □

The decline and fall of protein chemistry?

from Alan D. B. Malcolm

For more than 20 years the techniques of protein chemistry, including sequencing have played an enormous role in the development of biochemistry. It seems likely however that six papers in the *Journal of Biological Chemistry* (253, 5484; 1978) may be the zenith of this particular branch of science. These describe the complete sequence of β -galactosidase from *Escherichia coli*, which with a molecular weight of 116,349 is the largest protein so far sequenced. Its 1,021 amino acids gave rise to 72 chymotryptic peptides (*op. cit.* 5484), 24 cyanogen bromide peptides (*op. cit.* 5499) and 89 tryptic peptides (*J. biol. Chem.* 247, 5425; 1972) and the separation and ordering of these has taken A. Fowler, I. Zabin and colleagues at the University of California at Los Angeles eight years, and involved growing *E. coli* on [¹⁴C]lysine and [¹⁴C]arginine as well as [³H]methionine to increase the sensitivity of detection. The techniques of nucleic acid sequencing have developed so quickly that this is now much easier than protein sequencing—a fact which is acknowledged at the end of the last paper (*J. biol. Chem.* 253, 5521; 1978) where the authors state that the

sequence of the first 145 residues agrees with that predicted from the DNA sequence determined in W. Gilbert's laboratory at Harvard. It cannot be long before the rest of the DNA sequence is used to confirm or correct the protein sequence.

In this, the β -galactosidase sequencers have a problem similar to that of Ovchinnikov's group in Moscow who set out several years ago to sequence the subunits of RNA polymerase. They published the sequence of the α -subunit (molecular weight 36,512) last year (*FEBS Lett.* 76, 108; 1977) but before they could finish the two large subunits (β and β' , with molecular weights of 155,000 and 165,000) comes the news from Nomura's laboratory in Madison that part of the DNA is being sequenced thus making the protein sequence almost (but not quite) redundant. Nomura is using transducing phage λ *drif*¹⁸ which contains *rpoB* and *rpoC*—the adjacent genes which code for β and β' . Identification of precise start points for the protein on the DNA is made a lot easier by the fact that the N terminal tetrapeptide sequence has been known for some time (Fujiki & Zurek *FEBS Lett.* 55, 242; 1975) and it seems likely that the protein chemist will still have to provide such short sequences in the future.

Alan D. B. Malcolm is in the Department of Biochemistry, St Mary's Hospital Medical School, London.

An interesting illustration of the changeover from protein to nucleic acid sequencing may be seen in the analysis of the phage λ repressor (Sauer & Anderregg *Biochemistry* **17**, 1092; 1978) where the authors have used a combination of the classical sequential Edman degradation, the more recent gas chromatography-mass spectrometry peptide sequencing and also the partial sequence of the *cl* gene (which codes for the repressor) obtained by the Maxam-Gilbert technique. The entire sequence of 236 residues was determined in the usual way and 179 of these were confirmed by GC-MS. The DNA sequence was then used both as further confirmation and also to resolve a disagreement with previous authors (Beyreuther & Gronenborn *Molec. gen. Genet.* **147**, 115; 1976) over the amino acids present at positions 14, 40 and 42. Like the *lac* repressor, the λ repressor binds to DNA through its N terminus and this region is highly basic with clusters of lysine and arginine at 3-5, 16, 17, 19 and 24-26.

Molecular analysis of the *lac* operon and its control regions is yet closer to completion with the recent publication of four papers (*Nature* **274**, 762; 1978) which include sequences for the promoter of the repressor gene (Calos *Nature op. cit.* 762) and the sequence of the repressor gene itself (Farabaugh *Nature op. cit.* 765). In both these papers the problem of obtaining enough DNA has been overcome by cloning restriction fragments shown to contain the relevant sequences in the plasmid vector pMB9, and again a transducing phage, λ h80d*lac*, which carries the *lac* operon, was useful as the original source of the DNA. The sequence of the repressor gene suggested that two peptides had been overlooked in the original sequence of the repressor (Beyreuther *et al. Proc. natn. Acad. Sci. U.S.A.* **70**, 3576; 1973), and also suggests that Gln should be Glu at positions 164 and 215. Beyreuther has checked the protein sequence (*Nature op. cit.* 767) and has found the missing residues—two are from a CNBr peptide at positions 231 and 232 and the other eleven at positions 148-158 are part of a tryptic peptide. Thus not only is DNA sequencing faster, but it is also less likely to lose fragments as a result of their small size or insolubility.

Of course it is still easier to purify a particular protein than to purify and characterise a particular segment of DNA but the latter is becoming easier all the time. In *Cell* (**14**, 673; 1978), Montgomery *et al.* report the isolation of the yeast cytochrome *c* gene. Several *EcoRI* restriction fragments of yeast DNA were found to hybridise to a synthetic oligodeoxynucleotide complementary to a region near the NH₂ terminus of the protein. A comparison

with the fragments obtained from a structural gene mutant where a G $\rightarrow$ T mutation abolishes an *EcoRI* site enabled the fragment containing the gene to be identified. The sequence of the first 91 nucleotides agrees exactly with the protein sequence. It will obviously not be long before phylogenetic trees based on nucleic acid sequences totally displace the less meaningful ones based on proteins.

Even the methods such as chemical modification developed to identify the residues vital for a protein's function now have a powerful rival in the technique of site-directed mutagenesis developed in Weissmann's laboratory in Zurich. This involves using a restriction enzyme in the presence of ethidium bromide to introduce a cut in only one strand of the DNA and then using the fact that DNA polymerase I will hydrolyse from the 5' end and re-synthesise at the 3' end of the break. By allowing this 'nick translation' to occur in the absence of some of the deoxynucleotide triphosphates and in the presence of a nucleotide analogue such as hydroxy dCTP (HODC), the analogue may be incorporated just once at a predetermined position. Since HODC can base pair with either G or A subsequent generations will either

be wild type or have a mutation at this site and the properties of the mutant may now be studied. So far this has been used to convert the QB phage coat protein cistron initiation sequence AUGGCA to AUAGCA or AUGACA or AUAACA and to study the effect on ribosome binding (Taniguchi & Weissmann *J. molec. Biol.* **118**, 533; 1978; *News and Views* **272**, 397; 1978). Perhaps surprisingly a G $\rightarrow$ A mutation in the fourth position actually increases the efficiency of ribosome binding whereas a G $\rightarrow$ A transition at the third position totally eliminates binding. The double mutant binds weakly. It seems as though the ability of the mutant A at position four to hydrogen bond to a U next to the CAU anticodon on tMet-tRNA must be responsible. Weissmann has now applied this trick to the gene for rabbit β -globin (albeit in a plasmid rather than in the animal) (Muller *et al. J. molec. Biol.* **124**, 343; 1978). Such an approach will clearly have a tremendous impact on attempts to establish structure-function relationships for proteins. Custom designed mutants seem likely to make much of today's elegant protein chemistry seem very crude. $\square$

Astronomers licked by QSOs and active galactic nuclei

from John Faulkner and Martin Gaskell

A RECENT workshop on quasars and active galactic nuclei hosted by Lick Observatory provided not only an appropriate topic for discussion at this centre of optical and theoretical work on emission line objects, but also provided a forum for the exchange of views (and occasionally insight) derived from other wavelength regions. Important contributions were made towards the resolution of long-standing problems; in other cases recently discovered problems became even more acute.

The subject is bedevilled for the non-specialist by the terminology used to describe the vast subclasses of objects observed (QSOs, BSOs, OSQs, BL Lacs, OVV's, NLRGs, BLRGs, AO 0235+164 objects and so on). It was not always clear that many of the participants bore the numerous fine observational distinctions between these objects in mind in their discussions, or even whether they should have. There did seem to be a tacit assumption that all QSOs and active galactic nuclei

(AGNs) are indeed manifestations of varying degrees of the same phenomenon.

The similarities and differences between radio-selected QSOs and optically-selected QSOs (OSQs) were discussed by several participants. Techniques for finding OSQs are improving. Less than 10% of these are turning out to be 'radio-loud'; and of the latter only a very small fraction are extended sources, which prompted D. Weedman's remark that "it's just ironic that radioastronomers found QSOs". A. Savage (Royal Observatory, Edinburgh) emphasised the problems of personal judgment in the selection of objects from prism plates. For example, one person might preferentially find high red-shifted, another low red-shifted OSQs on examining the same plates. It is therefore not yet possible to compare directly the surface densities of radio QSOs and OSQs. It does seem, however, that the surface density of OSQs increases to fainter magnitudes without any cutoff, in contrast to radio QSOs which have a peak in their magnitude distribution. Both Savage and P. Osmer (CTIO) remarked that

John Faulkner and Martin Gaskell are at the Lick Observatory, University of California, Santa Cruz.

radio-loud QSOs are far more likely to be optically variable than are radio-quiet QSOs.

No doubts at all were raised over the cosmological interpretation of emission line redshifts. Indeed almost the last nail in the non-cosmological redshift's coffin was hammered in by the acclaimed work of A. Stockton (Hawaii), who gave strong evidence for an association of galaxies with bright QSOs. Furthermore he showed that the redshift distributions of the associated galaxies were essentially symmetric about the emission line redshifts—thus lending great weight to the formerly disputed notion that the QSO emission line redshift is a 'true' cosmological redshift.

An important recent development in the often frustrated application of QSOs to cosmology has been the discovery and employment of the 'Baldwin effect' (a correlation between the CIV line strength and continuum luminosity; see Baldwin *et al.* *Nature* **273**, 431; 1978; *News and Views* **273**, 428; 1978). At the workshop it became increasingly clear that the Baldwin effect is most strongly seen in flat-radio spectrum QSOs, for which it was in fact first established. Osmer, for example, has now found faint weak-lined QSOs so that 'violation' of the effect by the radio-quiet QSOs can no longer be entirely attributed to an optical selection effect. In addition Harding E. Smith (University of California, San Diego) has identified a new subset of steep radio spectrum QSOs possessing unusually steep optical spectra (and of intrinsic interest in themselves) which do not satisfy the Baldwin effect. Nevertheless, C. M. Gaskell (Lick Observatory) reported that the Baldwin effect does seem to be holding up well in the face of new data for the flat radio spectrum objects. However, the use of the relationship to derive a value for the deceleration parameter q_0 of well over 0.5 provoked perhaps the most lively controversy of the workshop. Some support for a q_0 of around 1 came from R. F. Green (Caltech) in his application of the Baldwin effect to satellite ultraviolet observations of two flat radio spectrum QSOs. This holds promise, as further data comes in from the International Ultraviolet Explorer (IUE), that a wider redshift range can be used and applied to cosmology. Naturally, for that application it will be important to demonstrate that evolutionary effects are either absent or can be correctly allowed for. In this respect the infrared observations of Puetter (University of California, San Diego) and the IUE observations of J. B. Oke (Caltech) and Green were important for showing the similarities between high and low redshift QSOs when regions of the same rest wave-

length are compared.

All these observations accentuated recent problems in understanding the relative intensities of the hydrogen emission lines in both QSOs and Seyfert galaxies. Problems which had arisen earlier on a comparison of lines in composite spectra (which might therefore be suspect if QSOs of differing redshifts were dissimilar) were brought into stark focus now as it became clear that the Ly α to H β line ratios differed from those predicted by recombination theory by a factor of ten, and that this could not be explained by simple external reddening alone. Despite the endeavours of H. Netzer (Texas) and R. London (JILA, Colorado), no single mechanism seemed able to produce the desired suppression of Ly α or enhancement of the Balmer lines.

The nature of QSO absorption lines (that is, whether they are due to intrinsic or intervening matter) remains unresolved. There are still a large number of unidentified lines, differing from QSO to QSO. A. E. Wright (A.A.O.) made the (serious) suggestion that progress might be achieved by assuming that all absorption lines blueward of Ly α emission which had formerly been assumed to be all Lyman lines, should instead be assumed not to be Lyman lines at all. A. Wolfe (Pittsburgh) reported the detection of a third 21-cm absorption line QSO.

G. K. Miley (Leiden) in collaboration with J. S. Miller (Lick), produced the first significant correlations between the optical spectra and radio morphology of QSOs. Extended sources have broader and more complex H β profiles. A direct outcome of the workshop was a collaboration between Miley and R. Angel (Arizona) which showed a striking correlation between the position angles of the optical polarisation and the large scale radio structure of the double sources.

No startlingly new theoretical ideas were produced, although many old scenarios have been pushed much further. In particular the detailed evolution of the dense nuclei of galaxies has been pursued by M. C. Begelman (Cambridge) and S. I. Blinnikov (Moscow). It seemed that all routes led to black holes.

The organisers had assigned M. J. Rees (Cambridge) the heroic task of chairing the session on complete models; a job which proved even more challenging when none was forthcoming. The model of R. D. Blandford (Caltech) and Rees, which tried to explain BL Lacertae objects as ordinary QSOs viewed with their highly relativistic jets pointing at us, met with firm opposition from the observers on whom these jets were supposedly aligned. □

A hundred years ago

The Sea-Serpent Explained

ON Monday, August 5, a number of geologists crossed in the Folkestone boat to Boulogne, to study the interesting formations of that neighbourhood, and, when about three or four miles from the French coast, one of these gentlemen suddenly exclaimed, "Look at that extraordinary object passing across the bow of the steamer, about a mile or a mile and a-half in advance of us!" On turning in this direction there was seen an immense serpent, apparently about a furlong in length, rushing furiously along at the rate of fifteen or twenty miles an hour; it was blackish in front and paler behind; its elongated body was fairly on the surface of the water, and it progressed with an undulating or quivering motion: *mirum erat spectaculum sane*.

Of course many suppositions were immediately started to account for this extraordinary phenomenon, but they quickly changed and settled into the fixed idea that the object before them could be nothing less than the great sea-serpent himself; for,—

"Prone on the flood, extended long and large,
Lay floating, many a rood, in bulk as huge
As whom the fables name of monstrous size,
Leviathan; which, God of all his works
Created hugest, that swim the ocean stream."

The writer fortunately had with him one of Baker's best opera-glasses, and, after a few moments' use of this little instrument, the wonder was satisfactorily resolved. The first half of the monster was dark and glittering and the remainder of fainter hue, gradually fading towards the tail. The glass did not determine the matter until the extreme end was reached, and then it was seen to consist of a mass of birds in rapid motion; those that were strong on the wing were able to keep well up with the leaders, and so make the head appear thicker and darker by their numbers, whilst those that had not such power of flight were compelled to settle into places nearer and nearer the tail. Doubtless these birds were shags (*Pelicanus cristatus*) returning to their homes for the night from the distant waters in which they had been fishing, during the day; perchance it may be wrong to assert positively as to the variety of bird, but inasmuch as the writer has often seen shags on the Cornish coast in smaller numbers returning in single or double file to their roosting places, and since it is stated in works of natural history that they have been noticed occasionally flying in this peculiar manner to the number of a thousand or more, it does not appear an unwarranted liberty in supposing that they really were *Pelicanus cristatus*.

Prospects for the use of amorphous semiconductors in solar energy conversion

J. I. B. Wilson & D. Weaire*

There is increasing interest in amorphous silicon as a low cost material for photovoltaic solar cells. Its possible uses extend to other methods of solar energy collection such as photothermal and photogalvanic conversion.

THE mutually stimulating but unpredictable interactions of pure and applied science are well exemplified by the history of amorphous semiconductors. These materials emerged from obscurity in the late 1960s, when new electronic switching devices, based on amorphous chalcogenides, excited widespread interest¹. Of course, this was not the first application of amorphous solids. They already had many uses, both mundane (for example, common glasses) and sophisticated (for example, amorphous Se, in xerography). Nevertheless, the inspiration for much of the concentrated academic activity in this area during the 1970s lay in the prospect of a new sub-field of electronics ('Ovonics') where the established picture of a crystalline semiconductor might not be at all relevant. Important new concepts have emerged, such as that of Anderson localisation², but the theory of amorphous semiconductors remains a difficult subject, rarely united happily with experiment³.

Small wonder then, that many have preferred not to jump in at the deep end by exploring the switching effect in the multi-component glasses. There have been obvious attractions in the study of the elemental amorphous semiconductors, particularly Si and Ge. It was, therefore, chiefly in the context of these comparatively simple systems that the debate between the rival microcrystalline and random network models of microscopic structure was conducted⁴. The consensus now favours the latter as the better conceptual basis for the description of amorphous Si and Ge.

There have been no important applications of amorphous Si and Ge (apart perhaps from optical coatings, where a wide variety of materials find a use). However, it has recently been shown that amorphous Si, when suitably prepared, can be used to make conventional semiconductor devices⁵. This was first demonstrated using the r.f. glow discharge decomposition of silane to deposit the amorphous film and varying the doping by the admixture of gases containing p-type and n-type dopant atoms⁵. It was then realised that the incorporation of hydrogen which is incidental in this process is essential for its success. Various other methods (such as sputtering⁶), suitably adapted to incorporate a small proportion of hydrogen, are under investigation. It remains to be seen whether the glow discharge process will be preferred when these alternatives have been fully explored.

The role of hydrogen is to reduce the density of electronic states in the gap region (typically from $10^{20} \text{ cm}^{-3} \text{ eV}^{-1}$ to $10^{18} \text{ cm}^{-3} \text{ eV}^{-1}$). These states are presumably associated with 'dangling bonds' in hydrogen-free samples, to which the hydrogen atoms are bonded when present. Figures 1 and 2 give an impression of the general nature of this material—a random network in which some of the Si atoms have one or more H atoms bonded to them.

In this article, we review some potential applications of amorphous Si in the field of solar energy conversion. These are not confined to the junction devices mentioned above, that is, solar cells, but these certainly constitute the most promising prospect.

How can such an intrinsically messy material have advantages over crystalline Si, on which so much of our device technology is already based? The answer lies in the anticipation of a comparatively low cost for the industrial production of amorphous Si in thin films of large area. In this regard, solar energy research runs

Fig. 1 Fragment of a random network model of amorphous silicon, in which tetrahedrally coordinated silicon atoms form an infinite non-periodic structure.

Fig. 2 Fragment of a random network model of hydrogenated amorphous silicon, with hydrogen atoms bonded to some silicon atoms.

counter to the trend of modern electronic device engineering in which 'small is beautiful'. The question then is whether acceptable efficiency and reliability can be obtained with an amorphous cell. This is still not clear but sceptics should be reminded that, had the single crystal window been invented first, they might be equally pessimistic about that familiar use of glass.

Photovoltaic conversion of solar energy

Photovoltaic cells, which convert light into electricity by a purely electronic process (that is, without chemical change) have been used for some years to power satellites. Indeed most of the development of high efficiency Si cells in the 1950s and 1960s derived from the needs of the space industry. They have also provided power in terrestrial sites where their convenience and reliability outweighs their high capital cost. Such applications will remain very limited until a much cheaper cell is developed. New research programmes in the US⁷ and Europe⁸ are aimed at this cost reduction.

All photovoltaic cells exploit the fact that a semiconductor will absorb radiation of sufficiently high frequency to excite an electron across the band gap, of magnitude E_g , and that electrons excited in this way return to the valence band ('recombine') only after comparatively long times (10–100 μ s).

In a p–n junction the energy levels associated with the valence and conduction bands vary in the manner idealised in Fig. 3, dropping by an amount E_g across the junction. Photogenerated electrons will move to the left (while the 'holes' left behind in the valence band move the other way).

If the junction is isolated (open circuit condition), the resulting charge imbalance will set up a potential difference V_{oc}

Fig. 3 Electronic energy levels at an idealised p–n junction. An electron–hole pair created by absorption of radiation near the junction is separated as shown (photovoltaic effect).

opposing the charge transfer. The system can only come into equilibrium when this exactly balances the change in electron energy levels at the junction, that is $eV_{oc} = E_g$ in our simplified picture.

This is the essence of the 'photovoltaic effect'. If the junction is incorporated in a circuit, a current I will flow and V will be correspondingly reduced. The power output is then simply IV and this is divided (for the optimum load) by the solar energy flux to give the maximum efficiency of the cell.

A narrow gap semiconductor absorbs most of the solar spectrum but wastes much of it as electrons are excited well above the gap and their surplus energy is merely converted into heat. On the other hand, a wide gap semiconductor fails to absorb at the infrared end of the spectrum. Thus the continuous frequency distribution of solar radiation (Fig. 4) enforces a compromise, favouring the choice of a semiconductor of band gap in the region of 1.5 eV. Even for this, the power efficiency is reduced to <50% by the waste at the low and high ends of the spectrum. Realistic models of junction behaviour¹⁰ reduce the theoretical efficiency to ~25% and practical considerations (grid contacts, and so on) reduce this figure still further. Most commercial Si cells achieve ~10–15%. The best laboratory result is 23% for GaAs cells in concentrated sunlight.

Schottky barrier solar cells are based on a metal–semiconductor junction (sometimes modified by the inclusion of a thin insulating layer at the junction). The essential structure of both types of cell is shown in Fig. 5.

Fig. 4 Spectrum of incident solar radiation at the Earth's surface, for normal incidence (AM1).

Commercially available cells at present use semiconductor wafers sliced from expensive single crystal boules. Two routes are being taken to reduce the cost.

First, the addition of lenses or mirrors to an expensive cell may produce a cheaper module by concentrating sunlight upon the cell. This approach is most appropriate when a large proportion of insolation is direct. It is of particular value in association with GaAs cells, which are efficient solar energy converters at higher operating temperatures than silicon.

Second, silicon for solar cells does not require such perfection and stringent purity control as for most other semiconductor devices and so polycrystalline boules or extruded ribbons may be of adequate quality. Taken to its logical extreme, this approach leads to the consideration of polycrystalline or amorphous thin films.

On the whole, polycrystalline thin-film solar cells, using a variety of semiconductors, have been disappointing. Often only fine grained polycrystalline films can be grown with unsatisfactory electrical behaviour due to grain boundaries. In other cases, it has been difficult to grow uniform defect-free films more than a few mm^2 in area, and sometimes the cells have shown excessive degradation after a short period of operation.

Amorphous silicon avoids some of these problems and even has certain marginal advantages over crystalline silicon. For instance, it has a bandgap 1.5–1.7 eV, closer to the optimum than that of crystalline silicon (1.1 eV), and furthermore absorbs radiation more strongly just above the gap. Radiation hardness is sometimes mentioned (particularly in the context of satellite power stations). However, while it may be true that "one of the unique properties of amorphous semiconductors is their low sensitivity to high energy radiation..."¹¹ there is relatively little in the published literature relating to this topic.

Current laboratory work is concentrated on the achievement of acceptable efficiencies. 'Acceptable' is generally taken to mean at least 8% but depends strongly on the application and its location.

Within a short space of time various p-n and Schottky cells based on amorphous Si have been reported with efficiencies of the order of 5%, as summarised in Table 1. Theoretical estimates of the limiting efficiency of such cells have ranged from 8 to 15%, and it seems reasonable to expect that the lower figure can be attained in the near future. The factor which is most significant in reducing the efficiency in comparison with single crystal cells is the short diffusion length of the charge carriers.

Table 1 Performance of amorphous silicon solar cells, under AM1 or similar conditions

Cell structure	Open circuit voltage (mV)	Short circuit current density (mA cm^{-2})	Efficiency (%)	Ref.
p-i-n	575	10.5	2.4	12
Pt-n	800	12	5.5	13
Ni-TiO _x -n	680	13	4.8	14

Only electrons and holes excited within about $1 \mu\text{m}$ of the junction survive to contribute to the photogenerated current. In a crystalline semiconductor the active layer may be as much as 0.5 mm thick. It remains to be seen whether this drawback is unavoidably inherent in the amorphous structure of the material or can be mitigated by refined preparative methods. However, little has been done (or, at least, published) on the optimisation of the doping profile close to the junction, which may yield some improvement.

It should be stressed that the results quoted above are for rather small area cells ($\approx 1 \text{ mm}^2$). It is a far cry from a laboratory cell of a few mm^2 to the orbiting solar power satellite suggested by Glaser¹⁵, with solar cells totalling 50 km^2 .

Photogalvanic and photochemical cells

Figure 6 shows the essential features of a photogalvanic cell. Again electrons are excited across the gap of a semiconductor at one electrode. Unfortunately most semiconductors with a suitable band gap are chemically unstable in electrolytes. TiO₂, a chemically stable compound which has featured in many studies, has a rather wide gap ($\approx 3 \text{ eV}$). Photochemical cells, in which TiO₂ has also been used; produce chemical fuels such as hydrogen from water. Promising results have recently been obtained with CdSe (ref. 16) ($E_g \approx 1.7 \text{ eV}$).

Amorphous semiconductors may offer new possibilities for such cells. Favourable factors are their ability to form strongly adherent thin films on a variety of substrates and low cost, which in this case might make regeneration economically feasible.

Photothermal conversion

Flat-plate solar collectors for heating water are installed in thousands around the world. These operate by the 'greenhouse effect', which is generally taken to mean that the selective transmittance of glass is the dominant feature. Most of the solar

Fig. 5 Schematic structure of: *a*, conventional n-on-p silicon solar cell; *b*, metal-semiconductor (Schottky) junction cell. The dimensions are typical of crystalline solar cells.

radiation passes through the glass but outgoing thermal infrared radiation, emitted by hot surfaces within the glass enclosure, is blocked. Consequently the temperature reached by an absorber plate is greater when a glass cover is in place. In practice the glass cover is equally important in reducing energy loss by convection, conduction, and evaporation, unless the temperature within is very high.

The cut-off point for transmission through glass lies around $3 \mu\text{m}$, so some solar radiation is excluded from the enclosure, but a longer wavelength cut-off would mean that more energy would be lost by radiation. A compromise is to make the cut-off as sharp as possible, at about $2 \mu\text{m}$. Although thin-film coatings can be applied to the glass to bring this about, there has been more interest in selective coatings for the absorber plate, for which the potential gain in collected energy is greater. A selective absorber will absorb visible radiation efficiently, but will not absorb infrared radiation. This means that equally it will emit visible radiation but not infrared.

Practical selective surfaces are generally semiconducting compounds, although their preparation may mean that their composition is obscure. Proprietary coatings include various Ni/Cr oxides/sulphides, which can have solar absorptances of up to 0.98 and infrared emittances of less than 0.2, even at the elevated operating temperatures.

Single-layer films such as these utilise the high infrared reflectance of a metal substrate (and consequently low infrared emittance) whilst providing an efficient absorber of visible radiation. It is only with multi-layer coatings that a sharp cut-off can be achieved, but this increases the complexity and cost of the

Fig. 6 Photogalvanic cell. An electron is removed from the electrolyte at the photo-cathode and one is injected into the electrolyte at the anode. Oxygen and hydrogen are evolved in this cell, by the simplified redox reactions shown.

collector. Semiconductors with a suitable bandgap for this application tend to have high refractive indices and are, therefore, a bad match to the low refractive index of air unless an anti-reflection coating is added. Sometimes it is possible to reduce the refractive index of a film by preparing it with a large density of minute voids.

The two drawbacks preventing the use of selective coatings on all flat-plate collectors are (1) their cost, and (2) their degradation at high operating temperatures. Degradation of absorber coatings may be caused by thermal expansion mismatch between film and substrate, leading to flexing, or by thermal migration of atoms between the film(s) and substrate.

Now, amorphous silicon produced by r.f. glow discharge decomposition of silane adheres very strongly to both metallic and ceramic substrates, because the plasma is an effective surface scourer. However its band gap is rather far from the optimum absorption cut-off of ~ 0.6 eV ($2\ \mu\text{m}$). Amorphous silicon films prepared by electron-beam evaporation in a vacuum chamber have such a high density of defect states within the bandgap that they will absorb energies further into the infrared. On balance it seems preferable to use glow discharge amorphous silicon, which can be made with a low free-carrier density (high electrical resistivity) and low 'gap states' density, and so use its low infrared emittance. Note, however, that amorphous semiconductors may be alloyed comparatively easily to tailor their optical properties. In this case, the solar absorptance of amorphous silicon may be improved by alloying it with boron¹⁷. It is expected that films of $\text{Si}_{1-x}\text{B}_x$ prepared by the glow discharge decomposition of SiH_4 and B_2H_6 may yield solar absorptances of up to 0.91 and infrared emittances of <0.09 even at the elevated temperatures reached by solar collectors.

At temperatures above $\sim 400^\circ\text{C}$, amorphous silicon may begin to recrystallise with some loss of the desired properties.

Significant changes should only occur after many years of collector use at this temperature. A second possible problem is that at these temperatures (which may be reached by concentrator collectors) hydrogen may be evolved from the film. Hydrogen evolution tends to decrease the bandgap¹⁸, which is not necessarily undesirable. Annealing of amorphous silicon films (that is prolonged periods at high temperatures) also seems to reduce the intensity of infrared absorption bands near $5\ \mu\text{m}$ (which are due to Si-H stretch modes), and so should reduce infrared emittance. This may prove to be a situation in which ageing is beneficial.

Characterisation of dielectric loss in solids and liquids

Robert M. Hill

Chelsea College, University of London, Pulton Place, London SW6, UK

The measured dielectric properties of a range of solids and liquids, as a function of frequency, have been examined and the loss has been shown to fit a generalised empirical relationship. This includes the Cole-Cole, Fuoss-Kirkwood, Cole-Davidson and Williams-Watts functions as particular cases and implies that a more generalised approach to the dielectric properties of materials is required than that given by the conventional distribution function extension of Debye's method, or by the dipole autocorrelation function of Williams and Watts.

OUR present understanding of the dielectric properties of materials is based on the Debye theory of a relaxing dipole interacting with an applied electric field¹. Early work showed that a set of exactly equivalent, non-interacting, dipoles characterised by a single relaxation time adequately explained the behaviour of weak dipolar solutions or dipolar molecules in the gas phase, but was insufficient to account for the broader frequency range over which dispersion was observed in solids and liquids in the frequency range below $\sim 10^{10}$ Hz. This difficulty was circumvented by the consideration of distributions of relaxation times² or by dipole autocorrelation³ in these more interactive media. These approaches have led to the situation where experimental measurements are analysed in terms of the

degree of fit to Cole–Cole, Cole–Davidson, Fuoss–Kirkwood, Williams–Watts or other empirical functions.

The results of a critical examination of the frequency dependence of the permittivity in a number of dielectric materials are reported here and compared with these standard functions. It is shown that the overall pattern of behaviour is broader than can be characterised by any one particular function and an empirical, but quite general, dielectric loss relationship is proposed and used to characterise the observed behaviour. The analytical method is based on the technique of temperature reduced variables⁴ with both logarithmic permittivity and frequency. The latter is common but the former is equally applicable and Jonscher⁵ has already shown that for frequencies greater than

Fig. 1 The real and imaginary components of the permittivity of pentachlorotoluene⁷ as a function of frequency. The diagram has been plotted in the form of a temperature reduced master curve to show the power law characteristics at frequencies below and above that of the peak loss. The scales are correct for $T = 293$ K and the curve shifts are given by the temperature labelled datum points at the top of the diagram. The curve through the loss characteristic is given by equation (1) with the parameters listed in Table 1.

the loss peak value, ω_p , both the real and imaginary components of the complex permittivity are proportional to $\omega^{-(1-n)}$, where ω is the frequency of measurement and n lies in the range between zero and unity.

By forming a master curve from the data over suitable temperature ranges the accuracy with which the pattern of permittivity behaviour, as a function of frequency, could be determined has been increased. In all cases clear evidence of power law behaviour with ϵ'' proportional to $\omega^{-(1-n)}$ for $\omega > \omega_p$ and proportional to ω^m for $\omega < \omega_p$ has been observed, a general relationship that is masked in the more common linear permittivity/logarithmic frequency plots⁶. Several empirical functions with these power relationships as limiting cases, were investigated and it has been found that the relationship

$$\epsilon'' \propto \frac{\omega^m}{(\omega_p^{2s} + \omega^{2s})^{(m+1-n)/2s}} \quad (1)$$

gave remarkably good agreement with the experimentally determined plots. The parameter s dominates in the region of the peak only, that is $\omega \approx \omega_p$, and determines the curvature between the decaying power characteristics, low values of s giving a broad, flat, peak in the loss. The parameters m , n and s all lie in the range between zero and unity.

Equation (1) obviously includes Jonscher's relationship at high frequencies. For the particular case of $m = (1-n) = s = 1.0$ equation (1) degenerates to the Debye case, and with $m = (1-n) \neq 1.0$ Cole–Cole and Fuoss–Kirkwood plots can be derived, as can the Cole–Davidson characteristic when $m = 1.0$ and in this case $\beta_{CD} = (1-n)$. The Williams–Watts plots of ϵ'' as a function of frequency³ also show the power characteristics but

in this case there is no simple relationship between β_{WW} and either of the gradients m and $(1-n)$ although increasing values of β_{WW} gives increasing values of both gradients.

Examination of experimental data

Published loss data for a range of dielectric materials, each over a set of temperatures, was plotted logarithmically on both permittivity and frequency axes. A single master curve was then constructed by pure translation, in both axes, for each temperature. The choice of axial shift was arbitrary, but minimal scatter in the reduced data points was sought. In a few cases both the real and the imaginary components of the permittivity were available and, as the translation is identical for each of these, this made the choice of axial shift more certain. Along with the experimental points a datum from the original plot was marked to give the magnitude of the translations. Note that the tracing technique gives the inverse of the temperature dependence for both the permittivity and frequency. The final master curve

Fig. 2 Temperature reduced plots of the permittivity of *a*, suprasil glass (J. le G. Gilchrist, personal communication) (scaled at 4.2 K); *b*, poly- γ -benzyl-L-glutamate⁸ (scaled at 326 K); *c*, water at 293 K (ref. 9). In all cases the curves through the loss peaks are given by equation (1) with the parameters listed in Table 1. The suprasil glass shows the frequency extent of the low frequency power characteristic. In (*b*) the dotted curve through the real part of the permittivity is a Kramers–Kronig transformation of the loss characteristic. The measured gradients of the loss characteristics for water are 0.963 and -0.968 indicative of a Cole–Cole process, but the specimen is clearly not Debye-like as the real component of the permittivity does not have a slope of -2.0 but obeys the Jonscher relationship in being parallel to the loss at frequencies greater than that of the loss peak.

contains only the information that was originally available but presented in a form that is more easily analysed, as the superimposition of a number of equivalent measurements reduces the experimental inaccuracies. In all cases the master plot showed a characteristic loss peak with linear wings, clearly indicative of the power law characteristics exhibited by equation

(1). The gradients m and $-(1-n)$ were determined and the parameter s chosen to give a good fit of the empirical relationship to the master curve in the region of the loss peak. In a few cases, where the real part of the permittivity was available, a Kramers-Kronig transform of the loss relationship, equation (1), was computed and excellent agreement with the experimental data was obtained for the real part of the permittivity.

Fig. 3 Temperature reduced plots of the permittivity of *a*, 2,4,6-tri-*tert*-butylphenol¹² (scaled at 293 K); *b*, butyl stearate¹⁴ (scaled at 273 K); *c*, liquid menthol¹³ (scaled at 317.6 K). All three specimens exhibit a low frequency slope of 1.0 and the curves through the data points are given by equation (1) with the parameters listed in Table 1. This behaviour is equivalent to a Cole-Davidson distribution of relaxation times.

Figure 1 shows the reduced plot for both the real and imaginary relative permittivity for pentachlorotoluene from the data given by Turney⁷. Jonscher's power relationship for frequencies greater than the peak with $(1-n)=0.64$ is clearly shown in the loss curve but the real component has merged with the infinite frequency value and could not be determined with any accuracy. The low frequency power relationship, with $m=0.87$ is well defined and the curve through the loss data points is the relevant plot of equation (1) with s equal to unity.

The extent of the low frequency relationship is shown by Gilchrist's measurements on Suprasil glass at very low temperatures (personal communication), Fig. 2*a*. In the reduced plot, six decades of frequency exhibit the characteristic, and again the degenerate form of equation (1), $s=1.0$, applies. The fully developed proportionality between the real and imaginary parts of the permittivity for poly- γ -benzyl-L-glutamate⁸ is shown in Fig. 2*b*. In this plot, as in Fig. 1, the real and imaginary components have been displaced arbitrarily on the permittivity axis for clarity. The ratio of the absolute values of the permittivities at high, reduced, frequencies shows the predicted $\tan[(1-n)\pi/2]$ relationship⁵. At low temperatures the low, reduced, frequency data show deviation from the power characteristic due to an increasing distortion from a second, lower

frequency, loss peak, the frequency separation between the two peaks decreasing as the temperature is lowered. The best fit master curve for the loss data required that s should be 0.9 ± 0.03 . The other parameters are listed in Table 1. In Fig. 2*b* as in Fig. 1, the temperature data lie on a straight line showing that there is a power relationship between the temperature dependence of the frequency shift, which is included in the term ω_p , the peak frequency, and the temperature dependence of the magnitude of the permittivity.

Fig. 4 A plot of the gradients m and $(1-n)$ determined for 50 loss peaks covering a wide range of polymeric and non-polymeric solids and liquids. Superimposed on the plot are the regions of validity of the Cole-Cole, Cole-Davidson, Fuoss-Kirkwood and Williams-Watts functions. Tables 1 and 2 list the gradient values.

None of these three plots show Debye, Cole-Cole or Cole-Davidson behaviour. The closest that has been observed to either Debye or Cole-Cole are the selected values of Mason *et al.*⁹ for water at 20 °C, which are presented in Fig. 2*c*. The deviation from equality in the magnitudes of the slopes, $m=0.963$, $(1-n)=0.968$, is within the accuracy of the determination of the slopes. The figure, however, shows a clear divergence from Debye behaviour in that the Jonscher relationship at high frequencies excludes the ω^{-2} decrease in the real part of the permittivity. Only if the loss decays exactly as the inverse of the frequency can the square law decrease be observed. The line through the loss data is, again, the empirical relationship. Ice at 181 K (ref. 10) and solid D₂O (ref. 11) have been observed to show similar equality in the gradients in log/log master plots and their characteristic parameters are given in Table 2.

Cole–Davidson behaviour, $m = 1.0$, has been observed in a number of materials, particularly when the loss peak has been observed in the frequency range from 10^7 to 10^{10} Hz. Figure 3 shows three sets of data with this characteristic, all of them from this frequency range, and all of them showing agreement with the empirical relationship. The characteristic parameters of these, and several other materials, are given in Table 1.

Some 40 materials have been examined using the technique described above and as some of these showed both α and β loss peaks about 50 loss characteristics have been determined. Figure 4 summarises the accumulated data in the form of a plot of m against $(1 - n)$. For clarity the points have been labelled and Tables 1 and 2 give a key to the data. It is apparent that the

distribution is not random but tends to cluster above the diagonal line $m = (1 - n)$. As well as the characteristic points the plot also shows the region of validity of the standard distribution and autocorrelation functions. The Debye characteristic is a single point, and is indicated by a square at (1, 1). The Cole–Davidson function requires that m should be unity and hence is given by the line along the top of Fig. 4, whereas the symmetry of the Cole–Cole and Fuoss–Kirkwood functions requires that data exhibiting this characteristic should lie on the diagonal from (0, 0) to (1, 1). The Williams–Watts expression is more complex, exhibiting a gradient of two for small values of β_{ww} and then smoothly merging with the upper limit for larger values of β_{ww} . The plot shows that although a small number of loss peaks lie on these characteristics the general distribution is much broader than these specific cases and that a more general approach to the nature of dielectric loss is required.

Conclusions

Our understanding of the dielectric behaviour in solids and liquids based on specific distributions of relaxation times or autocorrelation functions seems to be unsatisfactory. The force-fitting of experimental data into two or three types of behaviour is physically unfounded in view of the information presented in Fig. 4. The empirical loss characteristic proposed, equation (1), does not, at present, yield any physical understanding of the processes involved but has been shown to describe the experimental observations satisfactorily. The necessity for three parameters is clear as the loss curves are characterised by two power laws and a region of variable curvature. An empirical distribution function containing m , $(1 - n)$ and s could be generated but would contain no more understanding of the processes leading to loss than the empirical loss function itself. Rather, the function can be used as a test for new, more generalised, theories. One approach resulting in an expression for dielectric loss of the form of equation (1) will be presented in a later paper. Correlation of the parameters m , $(1 - n)$ and s , and of the temperature dependence of the frequency and permittivity datum shifts with the physical properties of the solid and liquid materials should begin to yield valid information on the precise nature of the interaction of electric fields and real materials.

Bedforms and their hydraulic stability relationships in a tidal environment, Bay of Fundy, Canada

Joseph J. Lambiase

Department of Geological Sciences, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061

Three intermediate- to large-scale bed configurations are recognised (from intertidal sand bodies in the Bay of Fundy), each with a discrete hydraulic stability field. Type 1 megaripples ('bars') form at lower flow velocities than Type 2 megaripples ('dunes'), whereas Type 2 megaripples and megarippled sandwaves are separated primarily by grain size. Megarippled sandwaves occur only in sands coarser than 0.308 mm.

TRANSVERSE sedimentary bedforms are produced by currents in many aqueous environments, and are of great interest to engineers and geologists. Because the complex nature of sediment-fluid interactions has prevented the development of a complete, theoretical understanding of bedform mechanics, attention has focused on empirical attempts to determine the hydraulic conditions governing bedform occurrence. Scaled-down flume experiments with steady-flow conditions have been used extensively¹⁻⁶. The results of such studies have greatly increased our knowledge of bedforms, but the much larger scale of most natural flows, and the unsteady conditions characterising them, limit the applicability of flume data to the real world. Complimentary bedform and hydraulic data from natural environments are needed.

This article presents a large body of such data, collected from intertidal sand bodies in the Bay of Fundy, Canada (Fig. 1). Bedform characteristics were recorded at approximately 760 locations and current velocity variations were monitored over complete tidal cycles at 110 stations. Nearly 3,000 vertical velocity profiles were measured. These data indicate that bedform development in this natural environment is more complex than that observed in flumes.

The study area

The investigations reported here⁷⁻⁹ were conducted in the eastern arm of the Bay of Fundy, on large intertidal sand bodies that occur in Cobequid Bay, the Avon River estuary, and along the north shore of the Minas Basin. The tides here are semidiurnal, anomalistic, and large, with a maximum measured range of 16.3 m at Burntcoat Head^{10,11}, and a mean range¹² of 11.9 m. Maximum water depths at high tide vary from 5 to 20 m, but depths at the times of peak current speed are generally between 2 and 10 m. The rate of water level rise and fall commonly exceeds 2 m h⁻¹.

Mean tidal current speeds ($\bar{U}$) vary greatly during each tidal cycle, and between neap and spring tides. The maximum speeds reach values of 0.5–2.0 m s⁻¹ during the middle to late part of the ebb tide, and in the first half of the flood. Cor-

responding maximum shear velocities fall between 0.03 and 0.15 m s⁻¹. The duration of peak flow strengths ranges from 1 to 4 h. The flow directions of the ebb and flood currents are generally 180° apart, but inequalities in the magnitude and/or duration of the opposing currents produce a persistent residual transport of sediment at most localities. Thus, either the ebb or flood portion of the tidal cycle dominates bedform formation and migration at any site.

The sediments on the sand bodies have mean sizes of 1.6–0.125 mm (–0.7 to 3.0 phi: very coarse to fine sand), but most are medium sand (0.5–0.25 mm: 1.0–2.0 phi). These sands exhibit good sorting, with standard deviations that are generally less than 0.8 phi units.

Additional information concerning the studied areas can be found in refs 7–9 and 13–16.

Bedform morphologies

Lower flow regime bedforms^{1,2} are abundantly developed on the sand bodies, and three basic types are recognised on the basis of size and morphology—ripples, megaripples, and sandwaves (Table 1). Upper flow regime plane bed^{1,2} is observed to occur during peak flow at only two locations in the Avon River estuary⁹.

Because of the great changes in flow direction, strength, and depth that occur during a tidal cycle, various modifications of the basic bedform types are produced^{7-9,13}, including: planing-off of megaripple crests in shallow flows; incomplete reversal of

Fig. 1 Map of the study area showing its location in the eastern arm of the Bay of Fundy (insert), and the extent of the intertidal zone at spring low tide (stippled pattern).

Table 1 Summary of bedform size and morphological characteristics

Bedform type	Wavelength (<i>L</i>) (m)	Height (<i>H</i>) (m)	Steepness (<i>L/H</i>)	Morphological characteristics
Small scale: Ripples	<0.3	<0.05	~10	Straight to linguoid in plan Usually superimposed on larger forms as a late-stage modification
Intermediate scale: Type 1 Megaripples	0.1–25.0 (6.1)	0.05–0.50 (0.18)	10–150 (44.6)	Straight to smoothly sinuous in plan, without small sinuous irregularities Lack scour pits Height remains constant along crestline Flattened in section (<i>L/H</i> usually >20) Wavelengths and heights poorly correlated ($r = 0.462$ for $n = 70$), with a best-fit regression line of $H = 0.0947 (L)^{0.346}$ Less faces at angle of repose, producing tabular cross bedding
Type 2 Megaripples	0.05–14.0 (4.3)	0.05–0.70 (0.28)	6–34 (16.5)	Generally sinuous to lunate in plan, but may be straight with small sinuous irregularities Scour pits usually well developed Height variable along crestline Profiles are steep (<i>L/H</i> usually <20) Wavelengths and heights well correlated ($r = 0.788$ for $n = 255$), with a best-fit regression line of $H = 0.0865 (L)^{0.787}$ Less faces at angle of repose, producing trough cross bedding
Large scale: Megarippled sandwaves	10.0–215.0 (40.6)	0.15–3.4 (1.86)	17–210 (44.1)	Straight to smoothly sinuous in plan Scour pits absent Height constant along crestline Lee face inclination generally 10°–20° Wavelengths and heights moderately correlated ($r = 0.791$ for $n = 58$), with a best-fit regression line of $H = 0.0635 (L)^{0.733}$ Megaripples (usually Type 2, but less commonly Type 1) are superimposed on the sandwaves
Rippled sandwaves	5.0–25.0 (12.9)	0.15–0.75 (0.38)	30–55 (36.6)	Morphologically similar to megarippled sandwaves but only have ripples or lower flow regime plane bed superimposed on their stoss sides

Average values of height, wavelength and steepness index (*L/H*) are given in parentheses. r = correlation coefficient; n = no. of data points.

megaripples; and superposition of current ripples on all surfaces (Fig. 2) during the decelerating stages of the ebb tide. To simplify the analysis, and make the results more directly comparable with other environments, these modifications are not considered here.

Ripples are the smallest bedform type (Table 1) with heights and wavelengths of less than 0.05 m and 0.3 m respectively¹⁷. All shapes from straight to linguoid are observed. Ripples most commonly occur superimposed on the larger bedforms, but they are found on their own in a few localities. Only the latter are considered in the hydraulic section below.

Megaripples¹⁸ (Fig. 2a, b) are analogous to the dunes of most authors^{1,17,19}, and are intermediate in scale between ripples and sandwaves (Table 1). All megaripples have a lee face that is at the angle of repose of the sediment during active migration, but otherwise show a wide variation in detailed morphology. We have, however, arbitrarily subdivided them into two varieties—Type 1 and Type 2 megaripples. No single characteristic can be used to distinguish between the two types, and a continuous gradation occurs between them.

Type 1 megaripples are simple in appearance, and are characterised by straight to smoothly sinuous lee faces that lack irregularities with a wavelength of ~2–3 m (Fig. 2a). Scour pits are not present in the troughs; consequently, lateral continuity is good, and the height is very regular along an individual bedform. The wavelengths of these megaripples are long relative to the height, giving them flat profiles with wavelength/height ratios generally greater than 20 (Fig. 3). In addition, the heights and wavelengths of Type 1 megaripples are poorly correlated (Fig. 3, Table 1).

Type 2 megaripples are more complex in appearance (Fig. 2b), and are generally sinuous to lunate in plan. Some straight-crested examples do occur, but these exhibit small, sinuous irregularities along the lee face with a wavelength ~2–3 m. The troughs contain well-developed scour pits (Fig. 2b), commonly separated by prominent spurs. As a result, bedform height varies considerably over short distances along the crestline. Type 2 megaripples have steep profiles, and on average they are higher and shorter than Type 1 megaripples (Fig. 3, Table 1). The heights and wavelengths of Type 2 megaripples are quite well correlated (Table 1).

Sandwaves^{13,14,20,21} are the largest scale of bedform (Fig. 2c), with average heights and wavelengths markedly larger than those of megaripples (Fig. 3, Table 1). Most sandwaves are asymmetrical, but their lee faces commonly have inclinations of only 10–20°. (This is believed to be a result of the reversing flows, as possible fluvial counterparts possess avalanche faces^{22,23}.) Sandwaves display many similarities to Type 1 megaripples: they are straight to smoothly sinuous in plan; their troughs lack scour pits; the height remains uniform along a particular bedform (Fig. 2c); and they have flattened profiles with wavelength/height ratios rarely less than 20 (Fig. 3); but the heights and wavelengths of sandwaves are moderately well correlated (Table 1). Complete morphological gradations are observed between Type 1 megaripples and sandwaves, but no such gradational relationship is seen between sandwaves and Type 2 megaripples.

Virtually all sandwaves bear megaripples (Type 2 forms generally) on their stoss sides, producing 'megarippled sandwaves' (Fig. 2c). These megaripples do not appear to be a

Fig. 2 Intermediate- and large-scale bedform types. *a*, Type 1 megaripples: note the simple plan geometry, absence of scour pits, and uniformity of bedform height (~ 0.2 m). *b*, Type 2 megaripples with well-developed scour pits and three-dimensional geometries. Metre stick at right for scale. *c*, Megarippled sandwaves: note the straight crestline and the lack of scour pits, other than those associated with the superimposed Type 2 megaripples. The megaripples on the sandwave crest have been partially rounded-off by wave action during emergence.

late-stage modification as are the superimposed current ripples. Instead, echo-sounder records show⁸ that the megaripples are present and active throughout both the semidiurnal and neap-spring tidal cycles at most localities. This megaripple-on-sandwave superposition seems, therefore, to represent an equilibrium co-existence, comparable to examples reported from both fluvial²² and shallow marine²⁴ settings.

In a few instances, only ripples or lower flow regime plane beds are present on the sandwave stoss sides. These forms, called rippled sandwaves, are smaller on average than megarippled sandwaves (Table 1), but are otherwise similar in morphology. Observations suggest that rippled sandwaves may be a disequilibrium form of megarippled sandwaves, because the former almost always occur in situations of decelerating flow: either as a neap-tide replacement of megarippled sandwaves that exist during spring tides; or as a transitional form between megarippled sandwaves and Type 1 megaripples, produced by bedform migration into an area of lower current strength and shallower water depth. In both cases, the superimposed megaripples disappear before the sandwave because of their smaller size and shorter lag time^{25,26}. During the prograde transition from Type 1 megaripples to mega-

rippled sandwaves, a gradual increase in bedform size commences at the same time as the superimposed megaripples appear, and rippled sandwaves do not occur as an obvious intermediate step. These observations may support experimental work suggesting that bedform destruction is a less 'efficient' and slower process than bedform generation²⁷.

Hydraulic relationships

Bedforms respond in some manner to all flows that are above the threshold of sediment movement, but lag behind changes in flow conditions because of the finite time required to reach a new equilibrium^{25,26}. As a result, it is difficult to determine a specific set of hydraulic conditions responsible for the bedforms observed in the study area, because flow conditions vary greatly over the semidiurnal tidal cycle. It is thought, however, that a reasonable approximation to these 'effective' conditions is obtained by assuming that the major bedforms are produced by the peak flow during the dominant half of the tidal cycle. This is the period when the largest amount of sediment is transported, and data⁸ on the variation of friction factors over the tidal cycle suggest that the bedforms approach equilibrium most closely at this time.

Therefore, representative 'average-maximum' values of the mean current speed ($\bar{U}$) have been calculated by averaging the three highest mean speeds measured in water depths greater than 2.5 m during the dominant half of each monitored tidal cycle. (The depth limit of 2.5 m was established because fast currents in shallower flows were observed to plane-off pre-existing bedform crests.) Average-maximum values of shear velocity (U_*) and stream power (ω) also were calculated in the same manner. The mean water depth was taken as the average of the depths in which the three maximum $\bar{U}$ values occurred. All of these data are summarised in Table 2, and phase diagrams involving water depth, mean current speed and grain size are shown in Fig. 4.

Figure 4 shows that a good separation of the bedform types is achieved using the above procedure. Some overlap does occur, but this is to be expected because of the complexity of the environment as compared to closely controlled flume experiments. One factor not previously considered that contributes to the overlap in terms of $\bar{U}$ is the variation of flow strength with tidal range. During neap and spring tides, the maximum current speeds may, for a few tidal cycles, fall outside the stability range of the bed configuration developed by the preceding average tides. Because of lag effects^{25,26}, the bedforms do not always achieve a new equilibrium, and thus exist 'metastably'

Fig. 3 Plot of bedform height (H) against wavelength (L). Envelopes to the observed values are given for Type 1 megaripples, Type 2 megaripples and megarippled sandwaves. The thin diagonal lines are contours of the steepness index (L/H). $\circ$, Type 1 megaripples; $\bullet$, Type 2 megaripples; $\square$, rippled sandwaves; $\blacksquare$, megarippled sandwaves.

Fig. 4 Bedform phase diagrams, constructed by the method outlined in the text. The dominant half of the tidal cycle was established by comparing average-maximum values of $\bar{U}$ for the ebb and flood. The bed configuration developed at each site was determined by direct observation during emergence and/or from echo-sounder records. Δ , Ripples; $\circ$, Type 1 megaripples; $\bullet$, Type 2 megaripples; $\square$, rippled sandwaves; $\blacksquare$, megarippled sandwaves; ∇ , upper-flow regime plane bed. **a**, Average-maximum mean current speed plotted against mean grain size. Data for all water depths are included. **b**, Mean water depth plotted against average-maximum mean speed. Only data for medium sand (0.5–0.25 mm; 1.0–2.0 phi) are included.

out of their normal stability field, thereby creating overlap. However, this does not obscure the basic hydraulic relationships.

In the study area, ripples occur alone, without larger bedforms, only where the mean sediment size is <0.25 mm (2.0 phi) and the average-maximum current speed is below 0.75 m s^{-1} (Fig. 4a). The upper flow regime plane bed field also is restricted to fine grain size (less than ~ 0.21 mm: 2.25 phi) within the range of velocities encountered.

Type 1 megaripples form in sands coarser than 0.18 mm (2.5 phi) at average-maximum mean speeds comparable to those producing ripples, and at flow strengths (as expressed by either $\bar{U}$, u_{*} , or ω) which are considerably below those producing Type 2 megaripples (Fig. 4a; Table 2). This flow-strength distinction between straight-crested (Type 1) and three-dimensional (Type 2) megaripples has been known qualitatively for some time¹⁷, but has not previously been quantified. The degree of separation of the two megaripple types in Fig. 4 is remarkable, given the gradational nature of the morphological transition between them. This indicates that the distinction used here is not only consistent, but also of potential genetic significance.

Megarippled sandwaves also form at higher flow strengths than Type 1 megaripples, but at a slightly lower average strength than Type 2 megaripples (Fig. 4a; Table 2). However, the overlap between megarippled sandwaves and Type 2 megaripples in terms of $\bar{U}$ (and also u_{*} and ω) is large (Fig. 4); and both bedform types form in an almost identical range of water depths (Fig. 4b), a finding which sharply disagrees with the results of a previous study²⁸. Clearly, mean grain size is the only major variable that distinguishes between these two bed configurations (Fig. 4a): sandwaves are restricted to sediments coarser than approximately 0.308 mm (1.70 phi); whereas

megaripples coexist with sandwaves at those grain sizes but occur alone in finer sands. (Some Type 2 megaripple points plot within the megarippled sandwave stability field in Fig. 4a, but most of these represent starved megaripples migrating over gravel lag or bedrock. It may be that sandwaves, like desert draas²⁹, require a minimum thickness of mobile sediment before their formation is possible.)

Rippled sandwaves have not been given a separate stability field in Fig. 4a and b, because they overlap considerably with Type 1 megaripples and to a lesser extent with megarippled sandwaves. This behaviour agrees with the earlier suggestion that rippled sandwaves are a retrograde form of megarippled sandwaves.

Discussion

Comparison of the current speed-grain size phase diagram developed for this natural environment (Fig. 4a) with those constructed from shallow (0.2–0.4 m) flume experiments^{6,30,31} shows a close similarity in the positioning and slope of the various phase boundaries, despite the vastly different flow depths. The flume studies reveal that the stability field of dunes gradually pinches out as the sediment size decreases, so that dunes do not occur at grain sizes finer than approximately 0.1 mm (3.3 phi)³⁰. If Type 1 and Type 2 megaripples are considered together, then a similar pattern is evident in Fig. 4a. In addition, the slope of the Type 1 megaripple phase boundaries in Fig. 4a matches that of 'sand waves' in ref. 31 over the corresponding range of grain sizes.

These similarities, plus the near-vertical orientation of the Type 1–Type 2 megaripple boundary in Fig. 4b, are clear evidence that water depth has little influence on bedform development, especially in flow depths as great as those encountered in the study area.

Table 2 Mean values of sediment and flow parameters characterising the occurrence of the various bedform types

Bedform type	Mean grain size (mm)	Average-maximum mean speed (m s^{-1})	Mean water depth (m)	Average-maximum shear velocity (m s^{-1})	Average-maximum stream power ($\text{kg s}^{-1} \text{m}^{-1}$)
Ripples	0.184 (2.44 ϕ)	0.603	5.37	0.035	0.739
Type 1 Megaripples	0.328 (1.61 ϕ)	0.687	5.57	0.044	1.800
Type 2 Megaripples	0.272 (1.88 ϕ)	1.052	6.00	0.082	7.628
Megarippled sandwaves	0.507 (0.98 ϕ)	0.955	6.45	0.065	4.748
Rippled sandwaves	0.369 (1.44 ϕ)	0.701	4.50	0.045	1.750

Examination of the hydraulic and morphological data indicates that Type 1 megaripples are equivalent to the 'bars' described by Costello⁶, whereas Type 2 megaripples represent the dunes of refs 6, 30, and 31. Confusion arises, however, because 'bars' are, unfortunately, also called 'sand waves', and are thought^{6,30,31} to be a smaller-scale equivalent of the large sandwaves reported from many natural environments^{13,20-22}. The positioning of the distinct megarippled sandwave field in Fig. 4a does not seem to support such a comparison, despite the many morphological similarities between sandwaves and Type 1 megaripples ('bars').

It has been suggested^{32,33} that sandwaves are large dunes, which are in equilibrium with deeper and faster flows than smaller dunes. The large overlap of the megarippled sandwave and Type 2 megaripple stability fields in terms of both speed and depth (Fig. 4a, b) strongly indicates that this interpretation is not valid, at least in the study area. The formation of megaripples and sandwaves in similar water depths (Fig. 4b, Table 2) also calls into question the generality of the commonly cited relationship between water depth and bedform wavelength³⁴, which forms the basis of the computational model of bedform lag developed recently by Allen^{33,35}. The results of such models must, therefore, be treated with caution until more is known about sandwaves and their genetic relationship to 'bars' and dunes. Clearly, further detailed study in natural environments is necessary until such time as sandwaves can be reproduced in flumes.

We thank G. V. Middleton for advice, assistance and continued interest. The research was supported by grants from the Department of Energy, Mines and Resources, and the NRC of Canada. Additional support in the form of NRC and Gulf Oil Company of Canada Ltd scholarships to R.W.D., a McMaster University graduate fellowship to R.J.K., and an Imperial Oil Company Ltd scholarship to J.J.L. is acknowledged. R.J.K. and J.J.L. thank Bedford Institute of Oceanography for the loan of field equipment. B. K. Levell and H. G. Reading provided constructive criticism.

Transformation of yeast by a replicating hybrid plasmid

Jean D. Beggs

Department of Molecular Biology, University of Edinburgh, Edinburgh, UK and Department of Cytogenetics, Plant Breeding Institute, Trumpington, Cambridge, UK

Chimaeric plasmids have been constructed containing a yeast plasmid and fragments of yeast nuclear DNA linked to pMB9, a derivative of the ColEI plasmid from E. coli. Two plasmids were isolated which complement leuB mutations in E. coli. These plasmids have been used to develop a method for transforming a leu2 strain of S. cerevisiae to Leu⁺ with high frequency. The yeast transformants contained multiple plasmid copies which were recovered by transformation in E. coli. The yeast plasmid sequence recombined intramolecularly during propagation in yeast.

PROCEDURES for cloning DNA segments in *Escherichia coli* by insertion into a plasmid or bacteriophage genome are now well established and have been used to isolate many prokaryotic and eukaryotic DNA sequences. However, many eukaryotic genes do not have counterparts in bacteria and therefore cannot be isolated by complementation of a bacterial deficiency, and

sequences involved in regulation or development may only be usefully studied in a homologous genetic background.

A yeast cloning system would be extremely useful for the isolation of genes and regulatory sequences from yeast and other eukaryotic organisms and for the genetic manipulation of commercially important yeasts. Recently yeast cells were transformed at a frequency of 10^{-7} transformants per viable cell using a derivative of the bacterial plasmid ColEI carrying the yeast *LEU2* gene which codes for β -isopropylmalate dehydrogenase¹. The transforming plasmid was apparently not present in yeast clones in the free or non-integrated form but was integrated into yeast chromosomes at more than one site.

I describe here the development of a highly efficient yeast transformation system using yeast-bacterial hybrid plasmids which are able to replicate and may be selected in and recovered from both *E. coli* and *Saccharomyces cerevisiae*. The hybrid plasmids incorporate a yeast plasmid, 2 μ m long (approximately 6 kilobases)²⁻⁵ which was previously cloned in bacteriophage λ and analysed by restriction endonuclease digestion to determine its suitability as a cloning vehicle⁶.

The yeast plasmid is present in many strains of *S. cerevisiae*

Fig. 1 Plasmid pMB9, the 2- μ m plasmids from *S. cerevisiae*, and the hybrid plasmids used to clone nuclear DNA fragments from *S. cerevisiae*. The physical map of pMB9 is essentially that described by Bolivar *et al.*¹⁵ and the *Hpa*I endonuclease target was mapped in this work. The tetracycline resistance gene is represented by Tc^r. The *S. cerevisiae* plasmid types A and B which are presumably interconvertible are represented as dumbbells with the inverted repeat regions corresponding to the stem portion. The sizes of *Eco*RI restriction digest fragments are given as kilobases and were reported previously⁶. The structures are shown of the four hybrid plasmids chosen for further cloning experiments out of the eight possible configurations. To construct these hybrid plasmids, purified¹⁶ yeast plasmid DNA was restricted with *Eco*RI endonuclease¹⁹ under conditions such that digestion was incomplete and the majority of the products were in the form of full length linear molecules as determined by agarose gel electrophoresis¹⁹. Plasmid pMB9 DNA purified from chloramphenicol-treated cultures²⁰ by a cleared lysate procedure²¹ was digested with *Eco*RI endonuclease and the two digested DNA samples were mixed and ligated²². *E. coli* strain ED8767 (*recA56 metB⁻ hsdS⁻ supE supF*; W. J. Brammar)²² was made competent by calcium chloride starvation²³ and transformed by heat shock treatment with DNA at 0.3 μ g ml⁻¹. Cells were diluted threefold with L-broth and incubated at 37 °C for 40 min before plating to select for transformants on fresh L-broth agar containing tetracycline hydrochloride at 15 μ g ml⁻¹. Transformant clones were screened for the presence of the yeast plasmid sequence by *in situ* hybridisation²⁴ with a ³²P-labelled probe prepared by nick translation²⁵ of DNA from a lambda clone of the yeast plasmid⁶. Clones of plasmids containing the yeast sequence were further analysed to identify those in which the complete yeast plasmid was present. The size of plasmid in each clone was estimated by gel electrophoresis of colony lysates²⁶. Clones with full-size hybrid plasmids were further characterised by restriction analysis of the plasmid DNA.

Fig. 2 Cloning of *leuB*-complementing sequences from yeast nuclear DNA into hybrid plasmids. *Eco*RI endonuclease digests of (1) pMB9 DNA, (2) pJDB36 (type A hybrid plasmid) DNA, (3) pJDB41 (type B hybrid plasmid) DNA, (4) pJDB248 (type A *leuB*⁺ plasmid), (5) pJDB219 (type B *leuB*⁺ plasmid) and (6) *Eco*RI endonuclease digest of λ DNA mixed with a *Hpa*I endonuclease digest of λ DNA. DNA fragment sizes are given in kilobases and faint bands are indicated by arrows. In the diagram only yeast sequences in pJDB248 and pJDB219 are shown. The yeast plasmid sequence is represented by a continuous line and the yeast nuclear DNA inserts by discontinuous lines. Arrows in the diagram represent sites for *Eco*RI endonuclease. Nuclear DNA (a gift from C. Christiansen) from *S. cerevisiae* strain M127 (prototrophic) was sheared in a Virtis 60K homogeniser²⁷ such that the major fraction of sheared DNA was in fragments 6 to 15 kilobases long with a smaller proportion of fragments of length ranging from less than 1 kilobase. A mixture of the DNAs of the hybrid plasmids pJDB36, pJDB41, pJDB45 and pJDB71 was digested with *Pst*I endonuclease. Both the yeast and the plasmid DNAs were extracted with phenol, extracted with ether and extensively dialysed against 0.1 M potassium cacodylate pH 7.0. Poly(dA) tails were added to the yeast DNA and poly(dT) tails were added to the plasmid DNAs by incubation with calf thymus terminal deoxynucleotidyl transferase. The reaction conditions were as described by Lobban and Kaiser²⁸, except that the temperature of the poly(dT) reaction was lowered to 0 °C, and in both reactions MgCl₂ was replaced by 0.5 mM CoCl₂ (ref. 29). The reactions were stopped by the addition of EDTA when 50 nucleotides had been incorporated per 3' terminus. The tailed DNAs (0.37 μ g of each DNA ml⁻¹) were annealed in 10 mM Tris, 1 mM EDTA, 100 mM NaCl pH 8 by incubating at 65 °C for 10 min and allowing to cool to room temperature in the same water bath. The DNA was cloned in *E. coli* JA221 by selection of tetracycline-resistant transformants. A total of 21,000 clones were stored in batches of 500 at -80 °C in 12.3 g per l K₂HPO₄, 0.9 g per l sodium citrate, 0.18 g per l MgSO₄·7H₂O, 1.8 g per l (NH₄)₂SO₄, 3.6 g per l KH₂PO₄, 88 g per l glycerol (D. Hogness, personal communication). In addition 5,000 of these clones were maintained individually in L-broth containing 7% dimethylsulphoxide in microtitre plates at -20 °C. Clones with plasmids complementing the *leuB6* mutation in *E. coli* JA221 were selected by growth of samples from the batches of clones on minimal selective plates (the minimal medium of Spizizen³⁰ was used with 0.2% w/v glucose, 1.5% Difco Bacto agar and 20 μ g ml⁻¹ L-tryptophan). The *leuB6*-complementing plasmids (pJDB219 and pJDB248) were analysed by digestion of the DNAs with *Eco*RI, *Hind*III, and *Hpa*I endonucleases and gel electrophoresis to determine the configuration of the hybrid plasmid in each case. Electrophoresis was through a 1% agarose horizontal slab gel (18 × 24 × 0.5 cm) in 40 mM Tris, 20 mM sodium acetate, 1 mM EDTA pH 8.2 at 100 V per 30 mA for 15 h. The gel was stained by soaking in a solution of ethidium bromide (0.5 μ g ml⁻¹) and photographed with a UV light source below.

Fig. 3 Autoradiograph of ^{32}P -labelled cRNA prepared³¹ to *EcoRI* digested DNA of pJDB248 (1, 2 and 3) or pJDB36 (4 and 5) hybridised with *EcoRI* digested pJDB248 DNA (1 and 4), *S. cerevisiae* DNA (2 and 5) or *S. cerevisiae* and pJDB248 DNAs together (3). The bands corresponding to the 1.5 kilobase DNA fragment are indicated by an arrow. The slower migrating bands (I, II, III) observed in the yeast DNA digests correspond to the supercoiled, nicked-circular and linear forms respectively of 2- μm yeast plasmid which was relatively resistant to digestion by *EcoRI* endonuclease although there were two targets for this enzyme in the plasmid sequence of this strain. Digestion of plasmid DNA with *EcoRI* endonuclease before the preparation of cRNA had the effect of increasing the efficiency of the RNA polymerase reaction, but the yeast sequences were then preferentially transcribed, resulting in the relatively lower intensity of the band due to pMB9 on the autoradiograph. The *S. cerevisiae* DNA used in this experiment was a different preparation from that used in the cloning experiment (and was prepared as described in the legend to Fig. 5). The possibility that the cloned DNA fragment was a contaminant in the DNA preparation is therefore unlikely. *EcoRI* digested DNAs were electrophoresed through a 1.5% agarose slab gel at 120 V per 45 mA for 13 h and transferred³² to a nitrocellulose filter (Millipore HAWP). Hybridisation of the filters was carried out at 60 °C in 4 ml $2\times\text{SSC}$ (0.03 M sodium citrate, 0.3 M sodium chloride, pH 7.0) containing 20 μg *E. coli* tRNA and cRNA (300,000 d.p.m.) with rapid shaking for 16 h. The filters were washed in $1\times\text{SSC}$ at 60 °C with gentle shaking for 2 h. The sensitivity of Kodak X-Omat H film was enhanced by using Ilford fast tungstate screens and storing at -80 °C during the exposure³⁵.

but has no known function. The plasmid has the same density as main band nuclear DNA^{2,5} and replicates under nuclear control^{7,8}, there being 50 to 100 plasmid copies per cell⁹. It contains an inverted repeat sequence 600 base pairs long and is isolated as a mixture of two forms which differ from one another in the orientation of the two nonrepeated segments of the molecule with respect to each other. The two forms are presumably due to recombination between the inverted repeat sequences¹⁰⁻¹². Plasmids isolated from several different strains of *S. cerevisiae* differ from each other by small deletions or point mutations which alter the restriction enzyme cleavage pattern of the DNAs^{13,14}.

Construction of chimaeric plasmids

The plasmids were constructed in two stages. First, pMB9, a derivative of the ColEI plasmid from *E. coli*¹⁵, and the plasmid from *S. cerevisiae* DR19/8T¹⁶ were joined by ligation of the DNA fragments produced by *EcoRI* endonuclease (Fig. 1). The pMB9 sequence includes a tetracycline resistance determinant and tetracycline-resistant clones were selected after transforming *E. coli* with the ligated DNAs. These clones were screened for a hybrid plasmid large enough to carry the complete yeast plasmid sequence.

Hybrid yeast-pMB9 plasmids theoretically have eight possible configurations. These are determined by whether the yeast sequence is in type A or type B configuration, by which of the two *EcoRI* endonuclease targets joins the sequence to pMB9, and by the orientation of insertion into pMB9. These configurations can be differentiated by the digestion pattern of the plasmid DNA with *HindIII* or *HpaI* endonucleases. Five of these different configurations were found amongst seven complete hybrid plasmids examined. The significance of the two forms (A and B) of yeast plasmid was not known. Nor was it known whether cloning DNA fragments into either of the *EcoRI* sites of the yeast plasmid would inactivate a sequence required for the maintenance of the plasmid in yeast or for some other essential function. Therefore, four of the different hybrid plasmids, pJDB36, pJDB41, pJDB45 and pJDB71 (Fig. 1), were used in the second stage of the construction of the plasmids to be used in the transformation of yeast.

Sheared nuclear DNA from *S. cerevisiae* of average fragment length 6 to 15 kilobases was linked by means of poly(dA-dT) tails¹⁷ to a mixture of DNAs of pJDB36, pJDB41, pJDB45 and pJDB71 which had been converted to linear molecules by digestion with *PstI* endonuclease. Tetracycline resistant clones were selected after transformation of *E. coli* JA221 (*recA1*, *leuB6*, *trpΔE5*, *hsdR⁻ hsdM⁺ lacY C600*; J. Carbon) with the annealed DNAs. A total of 21,000 clones were obtained, and those which were phenotypically *leu⁺* were isolated by selection on minimal plates. Two plasmids, pJDB219 and pJDB248, were isolated which contained a sequence able to complement the *leuB6* mutation in strains JA221 and C600. Both plasmids transformed strain JA221 to *leu⁺* or to tetracycline resistance with equal efficiency (10^5 transformants per μg DNA). The plasmids also complemented the *leuB61* and *leuB401* alleles¹⁸ at the same frequency as transformation to tetracycline resistance in the same strains.

Plasmid pJDB248 was pJDB36 with an insertion of approximately 2.4 kilobases containing two sites for *EcoRI* endonuclease which were 1.5 kilobases apart (Fig. 2). Plasmid pJDB219 was formed by an insertion of approximately 1.2 kilobases (containing one target for *EcoRI* endonuclease) in pJDB41.

Minor bands corresponding to DNA sequences of 3.8 and 2.9 kilobases were observed in varying amounts in *EcoRI* digests of different preparations of pJDB248 DNA from cultures produced from purified colonies. These corresponded to the fragment sizes expected if pJDB248 contained the type B yeast plasmid sequence rather than type A. Presumably the yeast inverted repeat sequences recombined during propagation in *E. coli*. This recombination was not observed in other *E. coli*-yeast hybrid plasmids. However, the rate of recombination may be slow relative to the growth rate of *E. coli*, and the growth of cultures from original clones was not extended beyond the minimum required for preparation of plasmid DNA.

Figure 3 shows that DNA from *S. cerevisiae* digested with *EcoRI* endonuclease contained a 1.5 kilobase sequence which hybridised to the ^{32}P -labelled cRNA prepared to pJDB248 DNA, but not to cRNA prepared to pJDB36. This indicates that the inserted sequence corresponds to a yeast DNA fragment. The same *EcoRI*-generated DNA fragment hybridised cRNA prepared to pJDB219, indicating that the *leuB*-complementing sequences in the two independently isolated plasmids were the same.

Transformation of yeast

S. cerevisiae MC16 α leu2-3 his4-712^{FS} ade2-1 lys2-1 SUF2; G. R. Fink (FS denotes a suppressible mutation, SUF2 is a suppressor gene) was used as the recipient strain to investigate the uptake and replication of the plasmids and the transfer of the Leu⁺ phenotype. Protoplasts and DNA were mixed and treated with polyethylene glycol to promote DNA uptake (see legend to Fig. 4). In different experiments between 10% and 30% of the cells thus treated regenerated the cell wall and produced colonies in supplemented minimal agar. Viable protoplasts were transformed to LEU⁺ by pJDB219 or pJDB248 DNA with a frequency of 5×10^{-4} to 3×10^{-3} transformants per viable cell. The leu2 mutation in this strain reverted to LEU⁺ at a frequency of only 10^{-8} to 10^{-7} . Clones transformed by pJDB248 grew as fast on selective plates as the untransformed cells grew on supplemented plates: protoplasts gave rise to colonies in 2 to 3 days. Transformants of pJDB219 required 3 to 4 days to develop colonies. [Note, efficiency of transformation of *S. cerevisiae* was not linearly proportional to DNA concentration, and a saturating DNA concentration was not found. Transformation frequencies of 10^4 to 10^5 transformants per μ g DNA were obtained in the conditions used here.]

To detect the presence of the transforming plasmids in yeast clones, extracts of yeast cells were analysed by gel electrophoresis, transfer of the DNA to nitrocellulose and hybridisation with a ³²P-labelled cRNA prepared to pMB9 DNA. Transformants T19.1 to T19.6 (Fig. 4) produced bands hybridising to the pMB9 sequence and with similar electrophoretic mobility to the transforming plasmid pJDB219 (upper and lower bands correspond to nicked circular and supercoiled molecules respectively, slower migrating minor bands probably represent

oligomeric forms of the plasmid). Transformants T48.1 to T48.6 also contained plasmids with the pMB9 sequence and with lower electrophoretic mobility than pJDB219, as expected for the larger plasmid pJDB248 (not shown in Fig. 4). There were apparently more copies per cell of pJDB219 than of pJDB248 in their respective transformant clones.

To investigate the integrity of the plasmid sequence in transformants, DNA was extracted and analysed by digestion with *Eco*RI endonuclease. Figure 5 shows the banding pattern of *Eco*RI-digested plasmid DNA isolated from two yeast clones transformed by pJDB219. The bands found in digests of pJDB219 DNA (corresponding to 5.3, 3.8, 2.5 and 0.8 kilobase DNA fragments) can be seen in the transformant DNA digests, and also the bands found in the digests of 2- μ m plasmid DNA (3.8, 3.6, 2.3 and 2.1 kilobase fragments). There is also a band in the transformant DNAs corresponding to a 4.0 kilobase fragment which would be expected if the yeast plasmid in pJDB219 recombined during propagation in yeast, converting a type B to a type A plasmid (fragments of length 3.8 and 2.5 kilobases would be replaced by fragments of length 4.0 and 2.3 kilobases). Thus all the bands in the plasmid DNA of one transformant (Fig. 5, track 2) are those expected for a mixture of the 2 μ m plasmid and pJDB219, however, two more bands can be seen in the plasmid DNA of the other transformant (Fig. 5, track 3) corresponding to 3.4 and 1.9 kilobase fragments. These bands cannot be readily accounted for. They may be products of recombination between plasmids¹¹, or of specific deletion events. Two examples of each type of banding pattern were found in digests of DNA from four different yeast clones transformed by pJDB219. The DNA from three yeast clones transformed by pJDB248 DNA was similarly analysed. The

Fig. 4 Autoradiograph of ³²P-labelled cRNA to pMB9 DNA hybridised with undigested DNA of lysates of yeast clones transformed with pJDB219 (clones T19.1 to T19.6) or pJDB248 (clones T48.1 to T48.6) and in the lysate of the untransformed recipient strain alone (0) and with pJDB219 DNA (p19). Cultures of *S. cerevisiae* MC16 to be transformed were grown on YPDA

(1% yeast extract, 2% Difco bacto-peptone, 2% glucose, 20 mg l⁻¹ adenine) and collected at 10^8 cells ml⁻¹. Cells were washed in sterile distilled water, concentrated threefold in 1.2 M sorbitol, 25 mM EDTA, 50 mM dithiothreitol pH 8 and incubated at 29 °C for 10 min with gentle shaking. Cells were washed twice by centrifugation and resuspension in the original culture volume of cold, sterile 1.2 M sorbitol. Protoplasts were obtained by concentrating the cells threefold in 1.2 M sorbitol, 0.01 M EDTA, 0.1 M sodium citrate pH 5.8 containing Helicase lyophilised snail gut extract at 2 mg ml⁻¹ (Industrie Biologique Francaise; 2 g powder containing 10^6 units β -glucuronidase activity were dissolved in 10 ml distilled water, filter sterilised and stored at -20 °C), and incubated at 29 °C with gentle shaking for 1 h. Protoplasts were washed by centrifugation and resuspension in the original culture volume of 1.2 M sorbitol three times to remove nuclease activities present in the snail gut extract, and resuspended in 1.2 M sorbitol 10 mM CaCl₂ to give approximately 10^{10} protoplasts ml⁻¹. DNA was mixed with 0.1 ml or 0.2 ml protoplasts to give 10 to 20 μ g DNA ml⁻¹ (DNA samples were sterilised immediately before use by extraction with chloroform and extraction with ether). Protoplasts and DNA were left at room temperature for 15 min and then diluted with 10 volumes of 20% polyethylene glycol 4000, 10 mM CaCl₂, 10 mM Tris-HCl pH 7.5 (a modification of a protoplast fusion procedure³³). After 15 to 20 min protoplasts were pelleted and resuspended in 100 μ l 1.2 M sorbitol, 10 mM CaCl₂, 20 μ g ml⁻¹ leucine plus 50 μ l YPDA containing 1.2 M sorbitol, and incubated at 29 °C for 20 min. Samples were diluted in 1.2 M sorbitol and plated by mixing in 7 ml minimal medium containing 1.2 M sorbitol and 3% agar at 45 °C (minimal medium was 0.67% Difco yeast nitrogen base without amino acids, 2% glucose, 20 mg l⁻¹ adenine, lysine and histidine) and pouring onto minimal medium plates containing 1.2 M sorbitol, 2% agar. Dilutions were plated on supplemented (20 μ g leucine ml⁻¹) minimal plates to measure the efficiency of protoplast regeneration. Colonies developed after 2 to 4 days incubation at 29 °C. To test for the presence of the transforming plasmid, single clones were purified on minimal selective plates. Single colonies were used as inocula to make 1 cm $\times$ 2 cm streaks on YPDA plates which were incubated at 29 °C overnight. These streaks of cells were resuspended in 0.5 ml 1.2 M sorbitol, 25 mM EDTA, 0.86 M 2-mercaptoethanol, pH 8, left at room temperature for 10 to 20 min and centrifuged. The pelleted cells were resuspended in 0.5 ml 1.2 M sorbitol, 0.1 M sodium citrate, 10 mM EDTA pH 5.8 containing Helicase snail gut extract at 2 mg ml⁻¹ and incubated at 29 °C for 1.5 h. Protoplasts were washed twice by centrifugation and resuspension in 1.5 ml 1.2 M sorbitol and finally resuspended in 200 μ l 10 mM Tris, 1 mM EDTA, 1% sodium dodecyl sulphate pH 8. Protoplasts were lysed by incubation at 60 °C for 20 min and debris was pelleted. Lysate (40 μ l) was mixed with 20 μ l 20% Ficoll, 0.05% bromophenol blue and electrophoresed through 1% agarose slab gels at 120 V per 35 mA for 15 h. Gels were exposed to short wavelength ultraviolet light for 15 min to nick the supercoiled plasmids and transferred to nitrocellulose filters as usual³², except that the denaturation step was carried out at 37 °C for 1 h to ensure plasmid denaturation and to hydrolyse RNA. The filters were hybridised with ³²P-labelled cRNA (300,000 d.p.m.) as described in Fig. 2.

Fig. 5 Autoradiograph of ^{32}P -labelled cRNA to *Eco*RI digested DNA of pJDB219 hybridised with *Eco*RI digested DNA from yeast clones transformed by pJDB219. (1) pJDB219 DNA; (2) DNA from yeast clone T19.1 in Fig. 4; (3) DNA from yeast clone T19.2 in Fig. 4; (4) DNA from the untransformed yeast strain. DNA fragment sizes are indicated in kilobases. DNA was partially purified from cultures grown on YPDA medium by lysis of protoplasts³⁴ and extraction of the lysates with phenol and chloroform. Nucleic acids were ethanol precipitated, resuspended, and RNA was digested by pancreatic ribonuclease³⁴. The samples were finally dialysed against 5 mM Tris, 0.5 mM EDTA pH 8.

unexpected 3.4 and 1.9 kilobase fragments were produced from the DNA of two of these clones (not shown).

Recovery in *E. coli* of plasmids from yeast transformants

Samples of DNA (prepared as described in Fig. 5) from six pJDB219 transformants were used to transform *E. coli* JA221. Transformed cells were plated on minimal agar, minimal agar containing tetracycline ($15 \mu\text{g ml}^{-1}$) or leucine-supplemented agar containing tetracycline. No significant difference was found between the transformation frequencies for the *leuB* and the tetracycline resistance markers selected either independently or together. This suggests that the plasmids recovered from yeast transformants by complementation in *E. coli* had retained both the tetracycline resistance and the *leuB*-complementing sequences. This test gives no information about plasmids which may have retained the *leuB*-complementing sequence but lost

the pMB9 sequence, as the yeast plasmid probably does not replicate in *E. coli* (J. D. B., unpublished result). Similar results were obtained in recovering DNA from pJDB248 transformants although the level of complementation was reduced probably as a result of the low copy number of plasmid in these strains (see Fig. 4).

DNA of the 'recovered' pJDB219 was isolated from eight *E. coli* transformants selected by transformation to *leu*⁺ and tetracycline resistance, and from two transformants selected for tetracycline resistance alone. The *Eco*RI digestion pattern of seven of these plasmid isolates was identical to that of pJDB219 DNA. Three of the recovered plasmids contained the yeast DNA sequence in the type A rather than the type B configuration. Since pJDB219 DNA used to transform yeast was in only one configuration (type B) this confirms the theory that recombination occurs in yeast between the inverted repeat sequences of the yeast plasmid. It can also be concluded that the yeast DNA sequence in pJDB219 complements the *leuB* mutation in *E. coli* regardless of the orientation of this sequence with respect to the pMB9 sequence (the inverted repeat sequences separate pMB9 from the *leu*-complementing sequence).

The results presented in this article show that *S. cerevisiae* can be readily transformed by the hybrid plasmids and that despite the generation of unexpected recombinant plasmids in some clones the unaltered plasmid can be isolated from the yeast clones directly, or purified by recloning in *E. coli* and prepared more easily from bacterial cultures.

The inheritance of the *Leu*⁺ phenotype in the yeast clones containing pJDB219 or pJDB248 has been shown by tetrad analysis to be cytoplasmic (J. D. B. and Nasmyth, K., in preparation).

Yeast is a desirable organism to use in molecular cloning. It is readily and rapidly propagated. Its biochemical and physiological similarity to bacteria allows the use of techniques developed for bacterial systems. It offers the advantage to genetic studies of vegetative growth in both the haploid and the diploid states. The high frequency of transformation obtained with the system described here makes it feasible to isolate directly in yeast any yeast DNA sequence from a pool of hybrid plasmids carrying fragments representing the entire yeast genome.

All experiments using organisms containing recombinant plasmids were carried out under category I containment as recommended by the UK Genetic Manipulation Advisory Group. I thank Professor K. Murray and Dr R. B. Flavell for laboratory facilities and many materials, and J. F. Atkins and J. R. Bedbrook for discussions. Most enzymes were provided by K. Murray and J. R. Bedbrook. Calf thymus terminal transferase was a gift from the Corporate Lab., ICI. The work was supported in part by an SRC grant. An EMBO Short Term Fellowship was awarded to develop techniques for regenerating yeast protoplasts in the laboratory of Dr P. P. Slonimski. J. D. B. is a Beit Memorial Research Fellow.

If your incubator kills your cultures, scrap the cultures.

Then scrap the incubator. And take a close look at Forma's new CH/P system CO₂ controller.

Hot-wire CO₂ sensors may corrode in high humidity maintained by your water-jacketed incubator. This erodes accuracy, creates CO₂ drift, increases consumption and complicates calibration.

Forma's CH/P System CO₂ Controller eliminates the hot wire sensors. CH/P is a mini-computer that thermally detects CO₂

tension, remembers your setpoint, and automatically calculates CO₂ input.

Only CH/P provides direct digital CO₂ setpoint and digital CO₂ display. CH/P linear electronics are a step beyond solid-state; this means quick and easy calibration and repeatable results. And a unique CO₂ Deviation Alarm guards against CO₂ drift from setpoint.

If it isn't Forma, it isn't CH/P. Now available on all Forma single and dual chamber water-jacketed CO₂ incubators.

now you can measure testosterone and dihydrotestosterone separately or together

Our new RIA kit is the simplest and fastest available for the assay of testosterone and dihydrotestosterone, separately or together in research applications in a wide range of biological samples.

To assay both androgens together a high specific activity tritium label gives the assay a very sensitive detection limit of 3 pg dihydrotestosterone per incubation tube. Also, a wide range of concentration levels can be assayed, up to 400 pg testosterone and 800 pg dihydrotestosterone per incubation tube.

Separation of the two androgens is achieved without the need for column chromatography by the use of a novel oxidation step which destroys the testosterone present. The assay of the unaffected dihydrotestosterone is achieved with a simple protocol incorporating a short incubation time of 2½ hours. Standards for both androgens are provided. Accurate results are obtained easily and quickly.

letters to nature

Atmospheric gravity waves generated during a solar eclipse

DURING a solar eclipse, the Moon's cool shadow, moving with supersonic speed through the Earth's atmosphere, should generate bow waves. In the experiments described here four microbarographs were used in an attempt to detect atmospheric pressure oscillations that were expected to accompany bow waves associated with the total solar eclipse of 23 October 1976. These internal gravity waves were found to have a peak-to-peak amplitude of 0.1 to 0.2 Pa, a period of 23 min and a velocity of $3.1 \times 10^2 \text{ m s}^{-1}$.

Figure 1 shows, in relation to the central line of the eclipse, the locations of the microbarographs at Tantanoola (T), Whyalla (W), Adelaide (A) and Kambalda (K), some hundreds to thousands of km apart. Their geographical coordinates are listed in Table 1. Four microbarograph records, sampled at 1-min intervals, are shown in Fig. 2. They all have dominant pressure oscillations at periods of the order of 20-25 min, with peak-to-peak amplitudes of 0.1-0.2 Pa. (Note that the microbarographs had broadband characteristics. Their maximum amplitude response was adjusted to be at a period of 6 min, which was approximately double their response to a 23-min period. It indicates that if other dominant periods had been present, these would also have been recorded.)

A microbarograph was installed at Kambalda (Western Australia) in anticipation that focusing of the bow-wave might occur in this locality due to curvature of the eclipse path and of the Earth's surface. In that case, a considerably greater amplitude would be expected at K compared with amplitudes at T, A and W which were well outside the expected focusing region. However, the present observations indicate similar amplitudes at all four stations, and give no suggestions of a focusing effect near K. The computation predicting focusing at K was subsequently found to be in error; S. Ball (personal communication) has shown that focusing of the bow wave should, in fact, have occurred at high northern latitudes.

At T, W and A, the weather remained fine throughout the recording time. At K, storms, accompanied by pressure fluctuations of 0.5-1.0 Pa amplitude, masked any bow wave recording except for the 2 h shown in Fig. 2.

To obtain a better estimate of the periodicity, a spectral analysis was made of each of the four records in Fig. 2. In every case, a period between 22 and 24 min was identified, the mean period being 22.7 min. This was the only periodicity common to all four records. It therefore seemed reasonable to attribute a 23-min period to a disturbance sufficiently widespread to affect all four stations, such as that generated by the eclipse.

As a further check that the 23-min period was associated with the eclipse, a comparison was made of the data shown in Fig. 3, namely the spectral components for T, which were: (1) derived for the nearly 5 h data in Fig. 2, including the eclipse interval and shortly afterwards; (2) derived for 83 min immediately before;

and (3) for 112 min immediately after the data in (1). (T was the only station for which data were available to make such a comparison.) The predominance of the 23-min period during and shortly after the eclipse, as indicated in (1), and its absence at adjacent times, confirms its association with the eclipse.

The present observation of 23 min is similar to the periodicity of about 20 min recorded^{4,5} in upper atmospheric disturbances after the eclipse of 7 March 1970.

An internal gravity wave of period 23 min should have a velocity⁶ of $3.1 \times 10^2 \text{ m s}^{-1}$. From this, and the known velocity of the eclipse 'point' along the central line of the eclipse path⁷, the positions of Q, T, S and R (called disturbance points) on the central line were estimated and are shown in Fig. 1. An eclipse-generated disturbance initiated at these points would arrive first at station K and then at T, A and W, respectively, before disturbance initiated elsewhere on the line. From the known times⁷ when the eclipse point moved through Q, R, S and T, an estimate was made of the times when the same phase of a bow wave should be recorded at K, W, A and T, respectively.

Table 1 Geographical coordinates of the four microbarographs

	Tantanoola (T)	Adelaide (A)	Whyalla (W)	Kambalda (K)

Comparative time (min) when eclipse was at dis- turbance point	20.5	17.75	15.5	0

Fig. 1 Locations of the four microbarograph recording stations (T, A, W and K) and the central line of the eclipse.

Fig. 2 Atmospheric pressure fluctuations recorded during and shortly after the eclipse at T, A, W and K.

The data were analysed further to confirm that the bow wave had the assumed velocity of $3.1 \times 10^2 \text{ m s}^{-1}$, and so to verify that an internal gravity wave was generated along the eclipse path. In the analysis, data from all stations were limited to the first 2 h plotted in Fig. 2, because useful K data were only available at that time. In estimating the bow wave velocity, it was convenient to imagine that a disturbance left Q, R, S and T simultaneously. To allow for the non-infinite eclipse velocity, an appropriate amount of time (indicated in the last row of Table 1) was subtracted from the actual times of recording for each station. The time difference between records from two stations, corrected in this way, is denoted t' . The interval, t' , between the occurrence of a particular phase of a disturbance at one station, and its occurrence at another station, is the time for a wave to travel between those stations. Knowing also the distance the wave has travelled, its velocity may be determined.

We wanted to estimate as accurately as possible the phase difference between each of the six pairs of records. To do this, cross-correlation coefficients, with time slips, were calculated for each pair of records. In Fig. 4, the cross-correlation coefficient, r , is plotted as a function of t' for the six pairs of records. (As an indication of the reliability of the data, note that the largest maximum in each of the TW and WK curves in Fig. 4 is statistically significant at the 5% significance level.)

Fig. 3 Spectral components of Tantanoola data recorded: (1) during and shortly after the eclipse; (2) immediately before data in (1); and (3) immediately after data in (1).

In principle, the value of t' at a particular correlation maximum for a pair of stations should be the time of travel of a bow wave from one station to the other, corresponding to the assumed velocity of $3.1 \times 10^2 \text{ m s}^{-1}$ ($=18.6 \text{ km min}^{-1}$). (Each curve in Fig. 4 has, in fact, several correlation peaks at approximately 23-min intervals, as expected. An acceptable correlation maximum would correspond to t' , giving a velocity of approximately the expected value.) However, the appreciable noise creates difficulty in accurately specifying the value of t' appropriate to a correlation maximum. To improve the accuracy, a sine curve of 23 min period was fitted to each cross-correlation curve. The arrows in Fig. 4 indicate when the sine curve giving best fit was a maximum, and these were taken to represent the correlation curve maxima.

The ordinate in Fig. 4 is d , the distance travelled by the bow wave from the first-mentioned station to the second. The six circles in Fig. 4 represent values of d as a function of t' , corresponding to correlation maxima. The circles for the station pairs AW, WK and AK lie close to a line of slope 18.6 km min^{-1} which passes through the origin. The observed time delays for those station pairs therefore affirm the assumed value for the bow wave velocity. The circles for the station pairs TA, TW and TK may be represented by a line of similar slope, but passing through $d = 0$ at $t' = -11 \text{ min}$. It seems significant that station T, on the central line of the eclipse, is included in all three of these latter station pairs. It suggests that the assumption of an atmospheric disturbance that occurred only on the central line of the eclipse is inadequate. In fact, the relevant width of the eclipse path was 174 km.

A cross-correlation analysis was carried out on the total T and W data in Fig. 2, extending over nearly 5 h. This gave a correlation curve maximum at $t' = 26 \text{ min}$, indicated in Fig. 4 by a square which lies close to the line of slope 18.6 km min^{-1} , passing through the origin. In contrast, the TW cross-correlation curve in Fig. 4, computed for only the first 2 h data, has a correlation maximum 11 min earlier.

Fig. 4 Cross-correlation coefficients (r), with time slips, are shown for the six pairs of stations. t' is the time slip of the first-mentioned station of a pair ahead of the second; t' has been 'corrected' to allow for the non-infinite eclipse velocity. d is the distance travelled by a bow wave between the two stations of each pair.

Both sets of points in Fig. 4 can be represented by lines of slope 18.6 km min^{-1} , which affirms that the observed velocity was as expected for an internal gravity wave of period 23 min.

An apparent discrepancy is the additional 11 min delay observed in the early phase of the bow wave received at T, compared with that received at A, W and K. This may be explained in terms of an initial disturbance that occurred north

of the central line of the eclipse, and travelled a longer distance to T and shorter distances to A, W and K than would have been the case for a disturbance on the central line. The difference in travel times, being 11 min, would locate the actual disturbance source at, or near, the total eclipse boundary. As the data in Fig. 4 are accurate to ± 2 min, the observation could imply a source location somewhere from ground level to stratospheric heights. The point arising in the present context is that the apparent 11-min discrepancy is explainable, and that the data which involve station T are not inconsistent with other data in affirming the expected internal gravity bow wave velocity.

First direct measurement of the beaming of Jupiter's decametric radiation

ONE of the most important features of the jovian decametric radioemission comes from the geometry of the observed radiation. The emission occurrence probability appears as a well defined function of the respective positions of Jupiter, the observer and the innermost galilean satellite Io, exhibiting several major sources which correspond to narrow ranges in zenocentric observer's longitude L (the so-called central meridian longitude) and in the synodic orbital phase of Io, Φ . These statistically established directivity properties were defined by Warwick¹ and Alexander², who showed that the repetition of the distinguishable dynamic spectra associated with each source occurring in a longitude range of 20° , is attributable to a $\pm 10^\circ$ beaming cone into which the radiation escapes in the ecliptic plane. Dulk³ stated more precisely that the emission is received on the Earth when Io makes certain angles with the line of sight, and that the dynamic spectrum varies in shape and frequency range with the magnetic longitude of Io. The beaming in latitude is also important⁴: the $\pm 3.3^\circ$ variation of the zenocentric declination of the Earth is sufficient to lead to a 15° variation of the statistical apparent sub-Io longitude of the emission. But these conclusions, based on statistics and on the repeatability of similar dynamic spectra in equivalent geometrical configura-

tions of Jupiter, Io and the observer, are not decisive, as they were obtained from a single direction at a given time. We present here the first direct experimental proof of a narrow beaming of Jupiter radiation, using simultaneous observations in two different directions, during the French-Soviet space radio astronomy experiment Stereo-5.

In this experiment, the Sun was simultaneously tracked from the Earth, at Nançay Observatory, and from the Soviet spacecraft Mars 7, at the frequencies 30 and 60 MHz (ref. 5). The observations were carried out for up to two hours per day, when the Sun was near the meridian at Nançay, from August 1973 to May 1974. During this period, the spacecraft was fitted with two linear antennas perpendicular to the ecliptic plane, which also allowed us to observe Jupiter. At 30 MHz, the antenna was a full-wave dipole; taking into account its efficiency and the electrical perturbation due to the spacecraft body, its effective gain was about 4 dB in the direction of the Sun, and much less in other directions. The signals were preamplified and detected by two automatic gain-controlled receivers with 0.5 MHz bandwidth and logarithmic responses. Both outputs were digitised at 4 Hz, and data were compressed and recorded on board, before being transmitted by telemetry to the USSR and then back to France. At Nançay, the equipment consisted of two 10 dB Yagis nearly orientated towards the Sun, feeding receivers of the same kind as on the spacecraft but with a 10 Hz sampling rate.

The broadband decametric Jupiter patrol at Nançay⁶ used a linearly polarised, log-periodic antenna, with a 10 dB gain, and a swept frequency spectrograph, covering the 20–40 MHz frequency, with a 15 kHz bandwidth and a sweep rate generally close to 10 Hz; in addition, a 1 MHz multichannel spectrograph⁷, tunable in frequency, was centred at 30 MHz during the stereo periods.

We were able to compare unambiguously two pairs of simultaneous track periods, 23 March 1974 and 15 May 1974, each free of solar activity (Fig. 1). On the first day, Jupiter was recorded on the Earth and not on the probe, and vice versa on the second day. These two cases, both of which correspond to the high frequency jovian Early source, are synoptically described in Fig. 2. The configuration in the solar system is displayed in Fig. 3. Note that, when giving flux densities or times for the spacecraft, we consider what would be seen by an observer on the line Jupiter-spacecraft at a distance of Jupiter equal to the Jupiter-Earth distance. From solar burst studies, we know that the sensitivity of the Earth is about four times that on the spacecraft for a source in the direction of the antenna maximum response (neglecting any problem of polarisation). We did not expect to receive many Jupiter events from the spacecraft, owing to the amount of available observation time. At 30 MHz, it emits for only a small percentage of time. It was also, for several weeks, pointing in directions of very low spacecraft antenna gain. Moreover, the solar activity often prevented any detection of the jovian emission. Hence we did not record Jupiter's activity when the stereo angle was small.

Fig. 1 Jupiter recorded at 30 MHz. On 23 March (a) the spacecraft is free of any activity; on 15 May (b) the Earth is free. The time scale for the probe is reset for a distance to Jupiter equal to that of the Earth at the same time.

Fig. 2 Synoptic diagram of the Stereo observations of 23 March ($\theta = 14.8^\circ$) and 15 May ($\theta = 16.4^\circ$). Light lines correspond to the periods of observations; heavy lines sketch the observed jovian activity periods; dashes indicate, for both days, the UT on Earth and on the spacecraft, taking into account the delay due to propagation; dotted lines are the occurrence probability contours, as drawn from 7 to 41 MHz (University of Colorado's data).

Nevertheless, all the features of the emission recorded by the spacecraft on 15 May 1974 are typical of Jupiter activity. The emission is absent at 60 MHz and present at 30 MHz, where it reaches a maximum flux density about $8 \times 10^{-21} \text{ W m}^{-2} \text{ Hz}^{-1}$. It was recorded for half an hour; it consisted of a succession of bursts, which look like the well known L -bursts, with a pseudo period of the order of 2 min, exhibiting strong intensity fluctuations on a very short time scale (the solar bursts never have so short a time scale). These fluctuations might correspond either to the interplanetary scintillation or to jovian S -bursts, averaged by the time detection constant of the spacecraft receiver. Of course, the slower modulation (L -bursts) is not an ionospheric effect, as is usually assumed from the ground, but is characteristic of the emission itself and probably corresponds to drifting spectral structures in the time-frequency plane.

At that time, in Nançay, Jupiter was not recorded either by the 30 MHz receivers or at any frequency between 25 and 38 MHz by the swept frequency receiver. At the end of the observation period, the planet was at a very large zenith angle in Nançay; but it was also tracked by the University of Colorado's spectrograph, between 7 and 41 MHz, and no emission was observed⁸ from 09.00 UT until 12.00 UT, above the sensitivity threshold $5 \times 10^{-22} \text{ W m}^{-2} \text{ Hz}^{-1}$. We can estimate that, during the whole ground observation period, there was no emission more intense than one-tenth of the intensity recorded on the spacecraft. This is to be related to the Jupiter stereo angle $\theta = 16.4^\circ$ (that is, the Earth-Jupiter-spacecraft angle), at this date.

Fig. 3 Projection on the ecliptic plane of the positions of the spacecraft, the Earth and Jupiter on 23 March (dashes) and 15 May (solid line). The radiation pattern of the spacecraft is indicated.

On 23 March 1974, Nançay recorded a strong Jupiter event, lasting 40 min, which reached about $3 \times 10^{-21} \text{ W m}^{-2} \text{ Hz}^{-1}$. It was visible on all the receiver outputs and showed rapid spectral structures. Aboard the spacecraft, whose sensitivity threshold was $\sim 10^{-21} \text{ W m}^{-2} \text{ Hz}^{-1}$, that is, one-third of the activity peak on the ground, no emission was recorded in the whole observation period. The stereo angle was $\theta = 14.8^\circ$.

Thus, both observations are the first direct evidence of the strong beaming of the decametric jovian emission: the recorded intensities, at the same instant, in two directions making an angle of 15° or 16° in longitude (and 0.2° or 0.4° in latitude) as viewed from Jupiter, differ by 5 or 10 dB at least.

Figure 2 shows in L - Φ coordinates the lines corresponding to the observation and emission periods, for the Earth and the spacecraft for the two days. The periods without emission correspond to regions of lesser occurrence probability.

In both cases, the spacecraft and the Earth swept the same ranges of longitude L , where the emissions occurred, whereas the ranges of Io-phase Φ were different. That seems to indicate that it is the 11° difference in Io-phase which causes the lack of correlation in the observations. Moreover, if we allow some possible variation in L -coordinate for the emission visibility, the

Fig. 4 Time variation of the departure angle between the observer and the magnetic field at the feet of the Io threaded magnetic flux tube; light lines, observation periods; heavy lines, emission periods. a, 23 March; b, 15 May.

Io-phase discrepancy was only 6° and 4° , respectively. Our observations may then be interpreted as an indication that the more rigorous angular condition comes from the position of Io on its orbit with regard to the observer. To illustrate this, supposing that the source of emission was at the northern or southern foot of the Io threaded flux tube (a generally accepted idea), we have computed (Fig. 4) the departure angle between the local magnetic field and the observer, using the D_4 -dipole model of Smith *et al.*⁹. On 23 March, this angle varies between 85° and 79° in the Northern Hemisphere (or 99° – 98° in the Southern) when the emission occurs on the Earth: aboard the spacecraft, during the observation period, the range was 78° – 61° (or 105° – 102°); on 15 May, the angle varies between 86° and 80° in the Northern Hemisphere (or 82° – 83° in the Southern) when the emission occurs on the spacecraft: on the Earth, the observed range was 110° – 86° (or 80° – 75°). Note that this angle differs by 9° at a given time between the Earth and the spacecraft and that, in any case, the ranges of variation overlapped. We conclude, therefore, that the decametric radiation should be emitted in a very narrow pencil beam, perhaps as narrow as a few degrees, which seems difficult to explain in terms of emission mechanism. We could imagine some strong propagation effects able to distort a less directive beam of emission.

The Stereo-5 experiment is part of a cooperative programme between the USSR (Intercosmos) and France (CNES). It was sponsored by Centre National d'Etudes Spatiales. We thank J. L. Steinberg, A. Boischot and J. W. Warwick for discussions.

Oscillations of the Sun and the geomagnetic field

THE suggestion by Toth¹ that the reported long-period oscillations of the solar atmosphere^{2,3} may be observed as oscillations of the geomagnetic field is an intriguing idea. It was suggested¹ that the ~ 2 h 40 min oscillations found in geomagnetic field data recorded at Tihany, Hungary, could reflect, through one of two possible mechanisms, similar period solar oscillations. In the first the geomagnetic field might have natural oscillations at this frequency that could produce environmental changes in the atmosphere^{4,5} and/or ionosphere and/or magnetosphere that would cause the ground-based telescope observations to reach erroneous conclusions. In the second mechanism the oscillations in the solar atmosphere might produce similar frequency oscillations in the interplanetary magnetic field which, through coupling with the geomagnetic field at 1 AU, would cause similar period variations in the field at the Earth's surface. Such oscillations would be in the range of periods of solar wind fluctuations measured near Earth and often attributed to Alfvén waves⁶. Regular, periodic variations in the interplanetary magnetic field with a

Fig. 1 Power spectra of six consecutive sets of 12 h of geomagnetic fluctuation data recorded at Durham, New Hampshire in 1975 (solid lines). The times and dates indicated for the spectra correspond to the local time of the station (LT $\sim$ UT $- 5$ h). The slope of the power-law fit through each spectrum is drawn. Dotted lines represent the low frequency portions of two spectra from Siple Station, Antarctica.

period near that of the reported solar oscillations have not been reported. We have spectral analysed geomagnetic field data on the same days as those published by Toth¹ using data from our fluxgate magnetometer stations in New Hampshire and in Quebec and data from the conjugate area at Siple Station, Antarctica⁷.

Our lowest latitude station (Durham, New Hampshire) is at the geomagnetic shell parameter $L \sim 3.2$; the highest latitude station (Girardville, Quebec) is at $L \sim 4.4$; Siple Station is at $L \sim 4.1$. Local time (LT) of our stations is $\sim$ UT $- 5$ h. The three components of the magnetic field are sampled at two second intervals and written digitally on magnetic tape. The instruments' noise levels are ~ 0.2 nT; the digitisation increment is 0.06 nT. We used our standard analysis method: the fast Fourier transform with a Thomson data window⁸ applied in the time domain. The geomagnetic observatory used by Toth in his analysis is located at $L \sim 1.9$, approximately 6 h east of the longitude of our stations.

Several spectra (12-h intervals) from Durham for 9–11 November 1975, the days reported by Toth¹, are shown in Fig. 1. Also shown (dotted lines) are the low frequency portions of Siple spectra for two of the time intervals. A power law frequency dependence $P(f) \propto f^{-s}$ was fit through each spectrum. The fits are shown superimposed on the spectra in the figures and the values of s for each spectrum are indicated. In none of these spectra do we find any evidence for a significant peak at a period of ~ 2 h 40 min. Because we find no significant spectral peaks in either the Northern Hemisphere data or in the conjugate (Siple) data, we can rule out a global magnetospheric phenomenon, driven either internally or externally, as the cause of the reported magnetic variations¹.

The data analysed here are expressed in power per unit frequency. At 10^{-4} Hz, the power level 10^5 nT² Hz⁻¹ corresponds to an amplitude of ~ 4 nT in a bandwidth of 2×10^{-4} Hz, an amplitude sensitivity comparable to the amplitude spectrum of Toth¹.

A relationship between the reported long period variations of the solar atmosphere and the geomagnetic field would have important implications for interplanetary field/geomagnetic field coupling, as well as for the solar wind flow in the inner heliosphere. However, we find no evidence of solar oscillations being reflected in the Earth's magnetic field on a global scale. The reported geomagnetic variations with a period of ~ 2 h 40 min must be local, related to geophysical sources in the vicinity of the observing station. We note a recent report⁹ that the envelope of modulation of geomagnetic pulsations in the period range 10–45 s as well as the auroral electrojet index AE had periods of ~ 2 h 40 min, possibly related to the solar oscillations.

Large baryon densities attainable in high energy nuclear collisions

NUCLEAR densities at least four and as much as 10 times normal should be achieved in U–U collisions with centre-of-mass kinetic energies between 1 and 4 GeV per nucleon, which would be much higher than previous discussions have indicated. Such collisions would give the best opportunity of making a stable or long-lived phase of high baryon density. It is suggested here that the accelerators at CERN would be well suited to explore the energy range of interest, both with fixed targets and with colliding beams.

Nuclear physics has traditionally focused on the properties of nuclear matter in or near 'normal' conditions, meaning those prevailing in known nuclei. The properties of systems with very high baryon density are unknown, although there have been interesting speculations about stable or nearly stable high density phases^{1–6}. In the absence of spontaneous transitions to such phases¹ (which might well be inhibited by enormous barriers) the only known way to produce high baryon density is to bombard heavy nuclear targets with heavy nuclear projectiles⁷.

Early theoretical discussions of such reactions were restricted to the nonrelativistic domain, with centre of mass (c.m.) kinetic energies much less than rest energies of the colliding nuclei. Density enhancements were computed by treating the nuclei as colliding drops of 'nuclear fluid', forming a shock front where they meet. These assumptions are valid for c.m. energies less than about 0.25 GeV per nucleon, at which the shock 'front' becomes as thick as the nuclei themselves, and a density less than four times normal is found for a plausible nuclear equation of state⁸.

The limitations on the shock wave approach suggested that higher energies could not generate still higher compressions. However, recent computations with a two-fluid model, in which bits of fluid at high relative velocity are coupled only by a frictional drag, indicated that high density could be attained during mutual interpenetration and slowing of target and projectile without shock formation⁹. An attempt to understand these results of complex numerical calculations has led to the following simple considerations, which assume minimum

compressibility and therefore give lower limits on the density enhancements to be expected at relativistic c.m. energies.

Uranium is a sufficiently large nucleus so that, at a 10–30% level of accuracy, a nearly head-on collision (≈ 0.1 b out of ≈ 7 b total reaction cross section) may be described as the meeting of two slabs 15 fm thick with nucleon density about 0.15 fm^{-3} . Of course, in the c.m. frame each slab would be Lorentz contracted, with density increased and thickness decreased by the Lorentz factor $\gamma = W/2M$, where W is the total c.m. energy and M is the mass of a uranium nucleus. Suppose that for a given γ each slab is thick enough to stop (in the c.m. frame) a nucleon in the other slab. Then the combined system will eventually be confined to a thickness less than $15/\gamma$ fm, because the back of either slab (assumed to have relativistic velocity) must progress at least halfway to the meeting plane before even a light signal from that plane could reach it. Consequently, at one moment the average baryon density will be at least 2γ times normal.

To get the maximum γ for stopping, note that a 40 mb nucleon–nucleon cross section corresponds to an average of nine interactions on crossing the slab. This number would be increased if repulsive correlations among the target nucleons were taken into account, but would be lower near the edges of the actual finite spheroidal nuclei. Suppose that the interaction probability is unchanged by previous collisions exciting the nucleon. A single high-energy nucleon–nucleon collision leaves a nearly uniform distribution in the fraction, x , of projectile momentum retained by a fast final nucleon¹⁰. If successive collisions had the same property, as they would for widely spaced target nucleons, then after N collisions the mean value of x would be $(N+1)^{-1}$, so that, converting to the c.m. frame, the stopping γ would be $1/2\bar{x} = (N+1)/2$, and the density enhancement would be greater than $N+1 = 10$ in our example. Barring an unexpected collective interaction between projectile and target, this estimate gives the upper limit on the stopping γ . A safe lower limit is $\gamma = 2$: at this γ , the target is contracted by a factor 7 in the projectile frame, giving a geometrical thickness just over 2 fm, so that in all relevant frames of observation there would be at least three collisions, each separated from the others by a time interval >1 fm (taking $C \approx 1$). This should be long enough for collisions to be independent, so that the effective N is at least 3, giving a stopping γ of 2 and making this a self-consistent lower limit. An indication of the most likely γ should come from analysing spectra of fast nucleons emitted in high energy nucleon–nucleus collisions. Such an experiment is underway at CERN (B. Povh, personal communication).

Farley¹¹ stated that the c.m. energy range 1–10 GeV per nucleon is important. As shown here, 1–10 GeV (rather than values around 0.25 GeV suggested by older work⁸) is the range in which one would expect to see a transition from stopping to transparency, or passage of the two nuclei through each other with some excitation and deceleration. If stopping were still found at 10 GeV per nucleon, that would be a remarkable discovery of a new collective effect.

From these arguments, CERN is a logical site for exploration of the high-baryon-density frontier. Uranium ions injected into the PS could be used in all three major installations at CERN (PS, SPS, ISR) for fixed target or colliding beam experiments in the c.m. energy range 1–10 GeV per nucleon. From the technical point of view, because low energy (MeV per nucleon) partly stripped uranium beams have been made at GSI in Darmstadt, the main new development would be acceleration to energies of a few hundred MeV per nucleon and full stripping of the ions. Studies for the Berkeley Bevalac indicate that this could be accomplished by substantially improving the vacuum of the booster which feeds the PS, with little if any modification in the PS itself (H. A. Grunde, personal communication). (A plan to generate 1 GeV per nucleon uranium at the Bevalac is expected to cost \$5 million, so that an effort on a similar scale at CERN would have a capital cost roughly 1% of the annual budget¹².)

Many questions remain about observation, interpretation and possible application of phenomena associated with high baryon

density. The central point is that an almost model-independent argument shows high density can be produced, and from previous experience, explorers of such a new domain may find rich rewards—perhaps even stable dense matter.

I thank the Los Alamos Scientific Laboratory, the Lawrence Berkeley Laboratory and the University of Sussex for hospitality during the development of this work, which was supported in part by the US Department of Energy, the NSF and the SRC.

Photoelectrochemical reduction of aqueous carbon dioxide on p-type gallium phosphide in liquid junction solar cells

THE non-biological reduction of carbon dioxide to organic compounds is of interest, as an alternative to natural photosynthesis, for the production of organic raw materials or fuel. In one approach, the required energy was supplied by irradiation with UV light, in the presence of ferrous salts, and resulted in the production of formic acid and of formaldehyde¹. In another approach, the energy was supplied from an external power source by electrochemical reduction of aqueous carbon dioxide. The reduction of carbon dioxide and production of formic acid during the electrolysis of sodium bicarbonate in aqueous solutions has also been reported², and a study of the reduction of carbon dioxide on a mercury cathode reviews earlier work³. Polarographic measurements on mercury electrodes showed that carbon dioxide, rather than the bicarbonate ion, is the electroactive species, with a half-wave reduction potential of -2.1 V (relative to SCE), and that formic acid is the only product⁴. We report here the photoassisted electrolytic reduction of aqueous carbon dioxide, achieved using p-type gallium phosphide as a photocathode, with part or all of the energy being supplied by light. The products were formic acid, formaldehyde and methanol.

Semiconducting solids have been intensively studied for their interaction with electrolytic solutions, and the theory of interaction of illuminated semiconductors with electrolytes has been reviewed⁵. In photoelectrochemical cells, the semiconductor electrode immersed in the electrolyte is connected through an external circuit to a counterelectrode. In p-type semiconductors in the dark, there are many holes in the valence band, but only a small number of electrons in the conduction band. Illumination by light more energetic than the bandgap increases the number of electrons in the conduction band. This increase in electron density in the conduction band results in a cathodic current⁷. Electron transfer to a suitable acceptor in the solution reduces this acceptor.

The photoassisted electrolysis of water to hydrogen and oxygen has been carried out using either p- or n-type semiconductors under illumination, with metal counterelectrodes as anodes or cathodes, respectively⁷⁻¹⁰. In these cases, an external electrical bias potential was needed to drive the reaction. The use of combinations of n- and p-type semiconductors such as n-TiO₂ and p-GaP, and the illumination of both electrodes, resulted in 'self-driven' photoelectrolysis cells not requiring an external bias¹¹.

The photoelectrochemical reaction system used in the present work consisted of a closed double-walled borosilicate glass beaker (about 30 ml capacity), with thermostat set at 25 °C, containing an aqueous buffer solution as electrolyte, into which dipped a photoelectrode consisting of a single crystal of p-gallium phosphide (Zn doped; resistivity 0.19 Ω cm; front surface area 0.24 cm²; etched for 1 min in concentrated HNO₃-concentrated HF-H₂O, 3:1:4 v/v; the ohmic contact to the back surface of the crystal was made by an indium-zinc solder. The back surface and the external lead were insulated using an epoxy cement). The counterelectrode was a carbon rod (6 mm diameter), and a saturated calomel electrode served as a reference. Carbon was chosen as the counterelectrode, as it was reported that formic acid and other C, H, O compounds were not oxidised on carbon electrodes². In some experiments, p-GaAs and p-Si were tested as photocathodes, but n-TiO₂ and n-Si were used as photoanodes. A light-beam from a stabilised high-pressure mercury arc or from a projector halogen lamp was focused with the help of a condensing lens on to the GaP crystal. Oxygen-free carbon dioxide (purified by passing through an aqueous solution of vanadous chloride) was continuously bubbled through the electrolyte. A side-port fitted with a rubber septum and syringe served to withdraw samples without opening the flask.

Using the above cell combination, both in the dark and under illumination, a measurable current through the external circuit could be obtained only by applying a cathodic bias to the p-GaP electrode (Fig. 1a). With the application of a cathodic bias of -1.0 V (relative to SCE) to the p-GaP, the initial photocurrent density was 6 mA cm⁻², whereas the dark current density was only 0.1 mA cm⁻². The photocurrent decreased gradually, but after 24 h stabilised at about 1 mA cm⁻².

Analysis of the electrolyte solution showed the presence of formic acid (analysed by reduction with magnesium and chromotropic acid assay¹³, as well as by alkaline permanganate titration¹⁴), formaldehyde (chromotropic acid assay), and methanol (gas chromatography on Poropak Q). After 18 and 90 h of irradiation, the concentrations of formic acid produced were 1.2×10^{-2} and 5×10^{-2} M, those of formaldehyde 3.2×10^{-4} and 2.8×10^{-4} M, and those of methanol 1.1×10^{-4} and 8.1×10^{-4} M, respectively. Thus, in contrast to the reduction of carbon dioxide on metal cathodes, the photoelectrolysis on p-gallium phosphide does not stop with the production of formic acid, but proceeds further, yielding formaldehyde and methanol. The approximate constancy in concentration of formaldehyde may indicate that this product reaches a steady state of formation and further reaction.

The efficiency of conversion of radiant energy into the chemical energy (optical conversion efficiency) of the reduction products of carbon dioxide was calculated by adaptation of the formula used previously^{9,10} for the photoelectrolysis of water to hydrogen and oxygen (in which each product is assumed to be formed exclusively):

$$\text{Optical conversion efficiency} = 100 I_c [(\Delta H/Z) - V_B] / I_a$$

where I_c = current density (mA cm⁻²); I_a = incident light intensity (mW cm⁻²); ΔH = heat of combustion (= 2.962, 2.639, 5.915 and 7.259 eV for hydrogen, formic acid, formaldehyde and methanol, respectively); Z = number of electrodes required in the reduction of one molecule of carbon dioxide to a molecule of product (= 2, 2, 4 and 6 for production of hydrogen, formic acid, formaldehyde and methanol, respectively); V_B = electrical bias (V).

Fig. 1 *a*, Current density (log scale) as a function of p-GaP potential (relative to SCE) for the cell carbon/K₂HPO₄-KH₂PO₄, 0.05 M, pH 6.8, CO₂/p-GaP. Illumination, high-pressure Hg-lamp, unfiltered; 210 mW cm⁻². *b*, Current density as a function of terminal voltage for the cell carbon/K₂HPO₄-KH₂PO₄, 0.05 M, pH 6.8, CO₂/p-GaP. Illumination: halogen lamp, filtered to transmit 365 nm band; *I*_a 2.4 mW cm⁻². *c*, Optical conversion efficiency (%) as a function of terminal voltage for production of CH₂O (x) and CH₃OH (O) in the experiment shown in (*b*).

In an experiment using filtered light of 365 nm wavelength (Fig. 1*b*), the maximal optical conversion efficiencies for production of either formaldehyde or methanol were thus determined to occur at bias voltages of -0.8 to -0.9 V (Fig. 1*c*), and were 5.6 or 3.6%, respectively. As only 17.3% of solar irradiance (at AM2) is in the near UV and blue regions (315–510 nm)¹⁵, and thus effective for exciting p-gallium phosphide (bandgap 2.25 eV), the maximal solar energy conversion efficiency to formaldehyde or methanol is calculated to be 0.97 or 0.61%, respectively.

In another experiment, an n-type polycrystalline TiO₂ semiconductor was used instead of carbon as the counterelectrode, and as electrolyte a 0.1 M solution of lithium carbonate (30 ml). After 16 h of illumination (unfiltered light of Hg-lamp) on both electrodes, maintaining a constant current of 0.50 mA (current density 2.1 mA cm⁻² on the GaP cathode), and letting the negative bias on the p-GaP cathode rise gradually from -0.86 to -1.4 V (relative to SCE), the solution reached a concentration of 1.0 × 10⁻³ M methanol (or 3 × 10⁻⁵ mol). Considering that six electrons are required for the reduction of 1 mol of carbon dioxide to methanol, this corresponds to a current yield of 60%.

Using a commercial silicon solar cell (2 × 1 cm² area) as an electrode, connecting its p-junction through an external lead to

the p-GaP crystal, immersing both electrodes in 0.1 M Li₂CO₃, and illuminating the n-junction of the silicon as well as the p-GaP, no external electrical bias was required, as the two photoelectrodes produced a sufficient potential to drive the reaction. After 38 h of irradiation in the presence of carbon dioxide, the initial current of 0.05 mA had gradually decreased to 0.01 mA. During this period, the concentrations of formaldehyde and methanol reached 2 × 10⁻³ and 3 × 10⁻⁴ M, respectively.

Photoassisted reduction of aqueous carbon dioxide was also achieved using a p-type gallium arsenide single crystal electrode. However, in this case the cathodic bias required was such that no net gain in energy conversion was obtained.

The mechanism of cathodic reduction of carbon dioxide presumably involves stepwise electron transfer reactions. The first stable product, formic acid, must be due to a two-electron transfer. Possibly, the mechanism is similar to that proposed for the reduction of carbon dioxide on mercury cathodes¹⁶,

In contrast to the electrochemical reduction of carbon dioxide on metal cathodes, which stops essentially at this stage because of the high overpotential for formic acid reduction, in the case of the photoelectrochemical reaction on p-type semiconductors, the further reduction of formic acid occurs readily, producing formaldehyde and methanol.

Further development of the application of semiconducting solids to the photoelectrochemical reduction of carbon dioxide may provide a new approach to the production of organic raw materials and fuel.

I thank Professor B. Pratt for the crystals of p-GaP and p-GaAs, Dr G. Hodes for the n-TiO₂, Dr J. Mandelkorn for the Si solar cells, and Professor F. Cardon, W. P. Gomes and J. Manassen and Dr D. Cahen for discussions.

Characterisation of organic acids trapped in coals

THE characterisation of trapped organic compounds which occur in geological materials such as coal and oil shale can provide an insight into both the origin of the organic matter and its subsequent modification through chemical reactions. Much work has been done on the isolation and identification of polar and nonpolar compounds in carbonaceous materials^{1–7};

however, aromatic acids in coals have received very little attention. Here we detail the characterisation and distribution of aromatic acids extracted from lignite and bituminous coals.

Freshly ground raw lignite from Sheridan, Wyoming was first treated with 5% aqueous HCl at room temperature to free the acids from the minerals¹, and then extracted with 2.5% aqueous sodium hydroxide at 35 °C for 16 h. After work up by the usual method¹, soluble organic acids equal to 2.6% by weight of the lignite were obtained. In the same conditions, only 0.23% of acidic compounds were recovered from an Illinois no. 2 bituminous coal. No organic acids were isolated from a Pennsylvania anthracite coal. The elemental composition and description of these coals have been given elsewhere^{7,8}.

A fraction of the organic acids isolated from the lignite was derivatised with diazomethane for analysis. Another fraction was derivatised with d_6 -dimethylsulphate⁹ to yield tri-deuteriomethyl-labelled derivatives. The derivatives were analysed by gas chromatography-mass spectrometry (GCMS), solid probe MS and high resolution MS using techniques which have been described previously^{7,10}. A gas chromatogram of the mixture derivatised with diazomethane is shown in Fig. 1 with numbered peaks identified in Table 1. The distribution of the organic acids as methyl esters was determined by measuring areas of GC peaks with a correction for the effective carbon number for each compound (Table 2).

Note that, as shown in Table 2, the alkaline extractable acids are qualitatively similar to those obtained from selective oxidation of the macromolecular material of the same lignite coal with $\text{aq-Na}_2\text{Cr}_2\text{O}_7$, (refs 7, 8), H_2O_2 - CH_3COOH (refs 7, 8, 11) or 15% HNO_3 (ref. 8).

Of particular interest is the identification of large amounts of benzene di- and tri-carboxylic acids and their derivatives which have not been found in the mild alkaline extracts of shale^{12,13}, lignin¹⁴⁻¹⁷, peat¹⁸ or humic acid^{14-17,19}. No C_6 - C_3 carboxylic acids (benzene ring with C_3 side chain)^{15,20} were isolated from coals, whereas these acids are commonly found in the extracts of the above. Note also that the phenolic acids identified have only one hydroxy group but no methoxy group. This was determined from GCMS and HRMS of the sample derivatised with d_6 -dimethylsulphate. This contrasts with the presence of di-, polyhydroxy, or methoxy benzene derivatives in the alkaline extracts or degradation products of the geological materials described above. The alkaline extract of bituminous coal was found to consist mainly of benzene di-, tri- and tetra-carboxylic acids (31.7% of the extract) and their methyl derivatives (39.9%), and naphthalene mono- and di-carboxylic acids (9.8%). Phenolic acids (2.2%), methylfuran di-carboxylic acid (2.9%) and aliphatic dibasic acids (4.5%) were also identified in small amounts. The remaining 9% has not yet been identified. No C_6 - C_3 carboxylic acids or benzoic acid were detected. Benzene and naphthalene carboxylic acids have been identified as major

products from the selective $\text{aq-Na}_2\text{Cr}_2\text{O}_7$ oxidation of the same coal^{7,8,21}. These facts may elucidate the reactions which occurred during the transformation of organic material from biopolymers (lignin, humic acid and so on) to geopolymers (coals). It is generally agreed^{1,15-17,22} that the essential reactions, including degradation of side chains, dehydrogenation, hydroxylation, demethylation, demethoxylation, cleavage of ring structures and polymerisation, occur during these transformations. Welte has suggested²² that at the stage of coal formation (early

Fig. 1 Gas chromatogram of the methyl esters of the carboxylic acid fraction from lignite coal. The analysis was carried out on a Perkin-Elmer 3920B gas chromatograph interfaced to a modified Bendix model 12 time-of-flight mass spectrometer with a continually variable split between a flame ionisation detector and the source of the mass spectrometer. The separation was made on a $15.2 \text{ m} \times 0.51 \text{ mm}$ SCOT column coated with OV-17 and temperature programmed over $100\text{--}250^\circ\text{C}$ at 4°C min^{-1} .

Table 2 Organic acids identified in the alkaline extract and oxidation products of lignite coal

Acid groups	Alkaline extract (%)	Oxidation product (%)		
		aq-Na ₂ Cr ₂ O ₇ *	H ₂ O ₂ -CH ₃ COOH†	15% HNO ₃ ‡
Benzenecarboxylic acid	16.6	59.2	36.1	63.3
Methylbenzene carboxylic acid	16.0	4.3	7.6	13.9

Terpenoid acid	6.6	—	—	—
Others	4.3	26.6¶	—	3.2
Unidentified	4.5	2.5	—	2.0

* 100% of coal was oxidised. 92% of total oxidation product is shown. The remaining 8% is humic acid-like material and nonacidic compounds.

† 80% of coal was oxidised. 50% of product is shown. The remaining 50% is humic acid-like material.

‡ 74% of coal was oxidised. 48% of product is shown. The remaining (52%) is humic acid-like material and nonacidic compounds.

§ Aromatic rings containing phenolic OH of lignite coal would have been destroyed by these oxidants except H₂O₂-CH₃COOH. The phenolic acid identified in these two oxidation products may be derived from aromatic rings containing methoxy group.

|| See peak nos 15, 27, 33 and 34 in Table 1.

¶ Carboxylic acids of naphthalene, phthalan, chroman, dibenzo-*p*-dioxin, xanthone, dibenzofuran and pyridine were identified (see refs 7 and 8).

** Several acids were identified but not estimated.

—, not found.

katagenesis), functional groups are lost and CO₂ and water are produced in coals, and hydrocarbons are formed simultaneously. The benzene mono-carboxylic acid and its derivatives identified in the extracts are thought to be largely degradation residues from biopolymers at early stages of coalification, whereas the benzene di- and poly-carboxylic acids and their derivatives and naphthalene-carboxylic acids are produced in later stages by oxidative degradation. Perhaps, in the geological environment, oxidative cleavage of C-C bonds proceeded along the periphery of the coal macromolecules with rupture of bridging linkages between aromatic units. The presence of aliphatic dibasic acids in the extracts suggests that they are derived, in part, from these linkages. Indeed, oxidation of lignite and bituminous coals with various oxidants^{7,8,21,23} gave benzene di- and poly-carboxylic acids as the most abundant products; however, little or no benzene mono-carboxylic acid was found in the products.

An alkaline extract of shale was found to yield alkylbenzoic acids and phenylalkanoic acids which resemble their cyclic terpenoid precursors^{12,13}. On the other hand, no ethyl or longer-chain alkylaromatic acids, or phenylalkanoic acids were found in the present work which apparently indicates that coal has undergone more rigorous geological changes than shale. Therefore, the aromatic acids may have undergone dealkylation leaving more stable derivatives.

We have found two diterpenoid acids in the lignite extract, dehydroabietic acid and its homologue, that are apparently derived from the diterpenoid resin acid, abietic acid, which is commonly present in the resins of conifers¹⁻³. They were identified as their methyl esters^{24,25} (GC peaks 35 and 32 respectively, Fig. 1).

These two terpenoid acids are the probable precursors for related diterpenoid hydrocarbons which we have characterised in the benzene-methanol extract of this lignite⁷.

Note the presence of several furan, benzofuran and dibenzofuran acids extracted from the lignite with 2.5% aq-NaOH. These compounds may have been derived from lignans¹⁷ such as furoguaiacin and pinosresinol which are commonly found in heartwood, or as suggested by Flaig¹⁵, they might be degradation products from dibenzofuran derivatives which were formed from condensation reactions of phenolic compounds during the coalification.

In the transformation from lignite coal to bituminous and anthracite coals, the present work and our previous work on the trapped hydrocarbons in coals⁷ indicate that the following reactions probably occurred. (1) Extensive degradation of phenols; very few phenolic acids (2.2%) were found in the alkaline extract of bituminous coal, whereas the alkaline extract of lignite coal yielded 40.4% phenolic acids. (2) Loss of carboxyl group; the bituminous coal extract contained much less acids. No acids were found in the extract of anthracite coal. (3) Dehydrogenation and partial dealkylation of side chains; demonstrated by the increase in abundance of methyl aromatic hydrocarbons and a decrease in the amount of terpenoid type hydrocarbons in the organic solvent extract of bituminous coal as compared to lignite⁷.

Thus, the macromolecules in bituminous coal contain a greater proportion of aromatic structure and greater degree of crosslinking than is found in lignite. Benzene tetra-carboxylic acids and naphthalene-carboxylic acids were found in the extract of bituminous coal.

The organic acids extracted probably are both oxidative degradation products and residuals of the original coalification process. These acids, in particular the aromatic acids, were found to be characteristic of coals and different from those acids derived from biopolymers.

We thank Professor R. C. Duty for helpful discussions. We acknowledge support from the Division of Basic Energy Sciences of the Department of Energy.

Synthesis and structure of synthetic zeolite ZSM-11

ZSM-5 (refs 1, 2) is a member of a new class of shape selective catalysts which have unique channel structures with 10-membered ring openings. These catalysts have unusual properties. They can selectively convert methanol to high quality gasoline³⁻⁶ and are used in commercially significant processes, such as distillate dewaxing, ethylbenzene synthesis, xylene isomerisation and toluene disproportionation^{5,7}. The framework of ZSM-5 (ref. 2) contains a novel configuration of linked tetrahedra consisting of eight five-membered rings. These configurational units may be linked through edges to form chains and the chains to form a three-dimensional framework which describes an intersecting channel system with openings

Fig. 1 Scanning-electron micrograph of a ZSM-11 crystal. Scale bar, 1 μm .

Fig. 2 Skeletal diagram of the A and B faces of the ZSM-11 unit cell. The c -axis is vertical. Oxygen atoms are not shown. The nearly circular 10-membered ring apertures shown are the entrances to straight channels which run parallel with the unit cell a and b axes.

intermediate between those in zeolite Linde type A and faujasite. We report here the synthesis and structure of another member of this family, ZSM-11.

ZSM-11 was hydrothermally synthesised in a system consisting of a quaternary compound, sodium oxide, an oxide of aluminum and oxide of silicon and water⁸. The single crystals of ZSM-11 have the characteristic morphology seen in Fig. 1. In the synthesised form, ZSM-11 has a typical empirical composition $[xR_4X + (1-x)M_{2/n}O]:W_2O_3:>10YO_2:ZH_2O$, where M is an alkali metal cation, W is aluminum or gallium, Y is silicon or germanium, R_4X is a cation of a quaternary compound of an element of group 5A, and $0 < x \leq 1$. Typical quaternary compounds used in the synthesis are tetrabutyl phosphonium chloride, benzyltriphenyl phosphonium chloride and tetrabutyl ammonium iodide.

The unit cell contents of the sodium form are $Na_nAl_nSi_{96-n}O_{192} \cdot \sim 16H_2O$, where n is < 16 . The resulting framework density is $17.6Si + Al \text{ k}\text{\AA}^{-3}$, compared with 17.9 for ZSM-5.

ZSM-11 crystallises in the tetragonal system with lattice constants $a = b = 20.12$ and $c = 13.44 \text{ \AA}$ which corresponds to

Fig. 3. X-ray diffraction patterns: a , computed from parameters in Table 1; b , of calcined ZSM-11.

average values derived from a least-squares refinement of X-ray powder diffraction data. The systematic extinctions $h + k + l = 2n + 1$ for hkl reflections and the merging of doublets into singlets provided two major clues that ZSM-11 was a species distinct from ZSM-5 and a body-centred tetragonal variation of orthorhombic ZSM-5 with space group $D_{2d}^{14} - I4m2$. Accordingly, a framework model was assembled using the chains in ZSM-5 (ref. 2), which satisfied these symmetry requirements. This was accomplished by connecting the chains together as mirror images of one another in both x and y directions (Fig. 2). In contrast, in ZSM-5 only one set of chains, in the bc plane, are mirror images of one another. The atomic positions of the silicon and oxygen atoms in this model were refined by least-squares techniques using the computer program DLS.⁹ This refinement adjusted the raw positional coordinates until the Si-O, O-O, and Si-Si interatomic distances fit the prescribed distances 1.61, 2.63 and 3.20 Å, respectively. The final positional parameters for this idealised model are given in Table 1. Comparison of the simulated powder pattern of the framework model with the X-ray powder diffraction pattern of the hydrogen form of ZSM-11 (Fig. 3) indicates that the framework model is that of ZSM-11.

In ZSM-5, linkage of chains occurs through 4-, 5-, and 6-membered rings, whereas in ZSM-11 this linkage occurs only through 4- and 6-membered rings. Nevertheless, the frequent

occurrence of 5-membered rings throughout the structure is believed to account for the high thermal stability of ZSM-11.

As in ZSM-5, the ZSM-11 framework contains two intersecting channel systems with 10-membered ring openings, but unlike those in ZSM-5 they are both straight and have the same elliptical opening with free diameter intermediate to those in Linde type A and faujasite (Fig. 4).

A preferred orientation of intrusion of Precambrian dykes

AN analysis of the original orientation of Precambrian dykes has produced a nonrandom pattern that implies the existence of a Precambrian stress field of global extent. In general, dyke intrusion tends to occur in a north-south orientation, and is concentrated in low latitudes. This distribution has many similarities to the present distribution of sheeted diabase complexes of present day oceanic ridge crests, and may reflect the persistence of the same stress field throughout geological time. Other evidence in favour of the existence of this stress field can be found in tectonic motions or geological features that exhibit a symmetrical distribution relative to the Earth's rotational axis. For example, Moore¹ showed that the preferred orientation of spreading axes is directed north-south with a secondary maximum orientated east-west. Active transform faults exhibit a unimodal east-west distribution. A former study of recent continental rift valleys has revealed a preferred north-south orientation of fracturing. Cainozoic grabens, most of which have not been significantly rotated by plate movements following their formation, exhibit an especially strong peak within 10° of north². Here we describe our analysis of preferred fracture orientations using the trends and directions of Precambrian dykes. A central point of this study is the assumption that regional dyke patterns record fractures which result from regional stress fields operative at the time of dyke intrusion. Escher *et al.*³ have confirmed the above assumption using geological evidence from the Amitsoq dykes of Greenland.

On observing that dyke strike and magnetic declination were often closely related, Strangway⁴, proposed that the planar shape of dykes affected their acquired remanent magnetisation direction. Thus it was suggested that dykes do not record the true field direction at the time of their intrusion. This theory can no longer be sustained for two reasons. First, positive contact tests show that the magnetisation of country rocks baked by the dyke intrusion retain the same remanence direction as the dyke. Second, palaeomagnetic poles derived from dyke rocks agree

Fig. 4 Comparison of the channel structure in a, ZSM-5 and b, ZSM-11

Fig. 1 Rose diagrams to show: *a*, the present distribution of the strike of Precambrian dykes; and *b*, the distribution of dyke strikes after correction to their original orientation.

well with poles derived from adjacent contemporaneous lava flows and sills.

If Strangway's initial observation were still valid, then an alternative explanation is required for the direct relationship between original dyke strike and its remanence direction. The obvious inference is that dykes are preferentially intruded in a north-south orientation and their apparent present-day random distribution is a result of complex plate rotations subsequent to each phase of dyke intrusion. Using the palaeomagnetic remanence declination (D) and the present day dyke strike (S_p), the original dyke orientation (S_0) should simply be $S_0 = D - S_p$. World Precambrian dykes, from Archean to Hadrynian, which have been studied palaeomagnetically⁵ were combined on two rose diagrams. The data for the diagrams include dykes from both the Northern and Southern Hemispheres. As strikes are bimodal, all points are plotted in the range 270–090°. Each spot represents a swarm of dyke intrusions (such as, the Abitibi swarm, and the Sudbury dykes). Where a dyke swarm is composed of a conjugate set this is represented by two points. Where more than one study has been reported from a particular dyke suite, this is plotted as only one point.

Figure 1*a* shows the dykes in their present orientation (S_p), and Fig. 1*b* shows the distribution of the corrected dyke orientations (S_0). A simple comparison shows that a random distribution of strikes in Fig. 1*a* is brought into a clear north-south orientation in Fig. 1*b*.

Evans⁶ has noted that with increasingly higher latitudes there is an increasing statistical chance of a coincidence between original dyke strike (S_0) and remanence declination (D). Thus a random sample of dykes from subsequently higher latitudes should show a progressively increased preference for a north-south orientation. Could this explain our observed distribution? It is highly unlikely. Applying the simple relationship between magnetic inclination and palaeolatitude shows that 85% of the dykes analysed in this study have palaeolatitudes below 50°, and 40% are within 20° of the Equator.

Fig. 2 Frequency distribution of the acute angle (β) between the dyke plane and the magnetic remanence vector. The theoretical curve after Evans⁶ is for a set of vertically intruded dykes with random strike. The over-abundance of low β observations suggests the preferred north-south orientation is of geological significance.

●, Theoretical; ▲, observed.

The observed frequency distribution (Fig. 2) of the acute angle (β) (ref. 6) bears no similarity to the predicted distribution given by Evans⁶ for random orientation of dyke intrusion. As shown in Fig. 2 the expected frequency of $\beta < 10^\circ$ on a random dyke orientation model is approximately half the observed distribution. Hence it would seem that the preferred north-south mode of intrusion genuinely reflects a feature of the Precambrian global stress field. The cause of this north-south preference of dyke intrusion remains obscure; however, we note that the distribution is very similar to that now observed with sheeted diabase complexes of the ocean ridges.

Finally, as shown in Fig. 1, much of the present apparent random dyke orientation seems due to post-intrusional rotation of continental blocks. Then, where dykes from adjacent cratonic blocks can be shown to be recording contemporaneous remanences, it would be simple to determine the amount of relative rotation between the blocks since remanence acquisition (dyke intrusion). Applying this method to several dyke pairs offers the possibility of defining the sense of motions of major fault systems through geological time.

Oxygen isotope palaeotemperatures from the Tertiary period in the North Sea area

THE understanding of global temperature conditions during the Tertiary period has greatly increased in the past decade owing to the successful oxygen isotope investigations of the numerous deep sea cores now available. Little attention has been paid, however, to applying the method to material from shelf sea areas, where the temperature-induced ^{18}O -record in carbonate shells are generally believed to be superimposed by ^{18}O -variations in water composition and by postdepositional alterations. This is unfortunate, as oxygen isotope data from coastal areas provide the best way of comparing traditional palaeoclimatological methods with the oxygen isotope procedure. The present study, which deals with the oxygen isotope composition of shell material from the Tertiary North Sea area, was initiated to overcome this lack of data. Here the oxygen isotope results are interpreted as palaeotemperatures and the first isotopic palaeotemperature curve for the Tertiary period in NW Europe is given.

The only reliable method of absolute palaeotemperature determinations is based on the temperature dependence of oxygen isotope exchange processes between water and shell carbonate¹. Most oxygen isotope palaeotemperature studies published recently have used foraminifera collected from the deep sea cores^{2,3}. Using foraminifera for palaeotemperature studies is difficult, however, in shelf sea areas. First the number of planktonic foraminifera is greatly reduced owing to the more restricted character of such seas⁴. Moreover, exchange processes affecting the original isotopic composition of the thin-walled foraminiferal tests are far more probable in diagenetic environments open to meteoric water than in deep sea samples.

The present study has been restricted to shell carbonate from molluscs. They are abundant as fossils in the area, and their size and often primary aragonitic mineralogy allow post-depositional alterations to be easily identified⁵. Moreover, they are known to secrete shell carbonate in isotopic equilibrium with the surrounding water⁶.

Oxygen isotope data have been obtained from samples of individual shells or combined shell assemblages collected in Tertiary strata in southern England, Holland, Germany, Denmark and southern Sweden. The material was dated by reference to the stratigraphic scheme summarised by Berggren⁷.

The isotopic results presented in Fig. 1 disclose a well defined pattern of variations in the ¹⁸O-composition of shell carbonate during the Tertiary period. This pattern, however, may reflect variations in oxygen isotope composition of the Tertiary North Sea water as well as in temperatures⁸. According to Shackleton and Kennett³, the accumulation of glacial ice on Antarctica has changed the average ¹⁸O-composition of ocean water by as much as 1‰ since middle Miocene time. Moreover, local deviations in oxygen isotope composition of seawater due to evaporation and fresh water mixing processes have to be taken into account. These processes vary in parallel to salinity^{9,10} and, consequently, palaeotemperature calculations have to be preceded by estimates of the salinity of the water in which the organisms grew their shells. This imposes a very severe limitation on the oxygen isotope palaeotemperature method, as no reliable procedure of palaeosalinity determination has yet been developed.

The present study has been restricted to material from faunal assemblages, the composition of which indicates normal marine environments at a certain distance from the coast. Minor fluctuations in salinity, however, are not detectable in this way. The average salinity in the Tertiary North Sea is assumed here to have varied within limits of 33–37‰, corresponding to variations in oxygen isotope composition of ~1‰ (ref. 10). The corresponding maximal error in isotopic temperatures is ~4 °C.

The palaeotemperature curve shown on Fig. 2 reflects these limitations. It is important to emphasise the fact that most of the ¹⁸O-data have been obtained from benthonic organisms and therefore reflect bottom temperatures rather than surface conditions. However, when compared to modern conditions the investigated assemblages in most cases represent soft-bottom communities of moderate depth (30–150 m) (ref. 11). At such a depth no well defined thermocline is thought to have developed and hence—as seen in the present day North Sea—bottom temperatures are supposed to be good approximations to mean annual surface temperatures.

The isotopic palaeotemperature curve (Fig. 2) illustrates water temperatures in the southern part of the Tertiary North Sea. Temperature minima are seen in Palaeocene time (NP 4–6), middle Oligocene time (NP 22–23) and late Miocene time (NN 10), while warmer conditions prevailed in Pliocene, early and middle Miocene and specifically in Eocene time. Minor fluctuations on the curve probably reflect variations in the isotopic composition of the North Sea water.

Several studies dealing with the changing character of fossil floral and faunal communities have revealed that long-term climatic fluctuations occurred in NW Europe during the Tertiary period^{12–14}. According to these studies subtropical climates in Palaeocene time and warm subtropical to tropical conditions in Eocene time were followed by a gradual decline in temperatures, leading to cold temperate conditions at the end of the Pliocene period. Compared to these data, the temperature variations seen in Fig. 2 indicate a more drastic pattern than hitherto described.

The present curve shows discrepancies between palaeotemperature and palaeoclimatological data specifically in Oligocene time. Water temperatures are seen to have declined rapidly in the North Sea about 36–38 Myr ago. This decline may reflect the onset of cold-water circulation in the Norwegian–Greenlandic Sea initiated by the opening of the strait between Greenland and Svalbard at anomaly 13 time (37–38 Myr ago)¹⁵. However,

Fig. 1 The oxygen isotope composition of calcium carbonate from molluscan shells collected in Tertiary outcrops and borings in NW Europe. The horizontal bars illustrate the uncertainty in dating the analysed material. Oxygen isotope determinations have been carried out by the usual analytical procedures, material has been roasted *in vacuo* and treated with 100% phosphoric acid at 25 °C. Analytical precision better than ±0.1‰.

Fig. 2 Isotopic temperatures calculated from average oxygen isotope values for each locality investigated. Shaded area represents limits of uncertainty due to local variations in the oxygen isotope composition of the Tertiary North Sea water. True Tertiary water temperatures are believed to be within the shaded area. The difference between the non-glacial and the present temperature scales is caused by the shift in average oxygen isotope composition of ocean water, owing to the accumulation of glacial ice on Antarctica. According to Shackleton and Kennett³ the Antarctic icecap reached present day magnitude early in the middle Miocene.

convincing evidence from other parts of the world indicates a drastic global cooling event at the beginning of the Oligocene period, probably triggered by the development of the cryosphere¹⁶⁻¹⁸. If the unresolved problem of the stratigraphic position of the Latdorfian substage (Upper Eocene or Lower Oligocene) in NW Europe were taken into account, the isotopic shift observed between shell material from Latdorfian and Rupelian deposits may prove to be contemporaneous with the global cooling event. Thus, the low water temperatures in the Oligocene North Sea may be interpreted as being in phase with global climatic changes.

Further investigations should concentrate on the comparison between palaeoclimatological data obtained by traditional methods and the oxygen isotope curve, specifically for the Oligocene period where the extensive climatic modifications are expected to have influenced faunal and floral compositions much more than previously acknowledged. Moreover, the precise identification in NW Europe of the Oligocene global cooling event could prove to be a valuable chronostratigraphic tool in the solution of the Latdorfian Problem.

Oxygen isotope measurements were performed at the Geophysical Isotope Laboratory, University of Copenhagen. Part of the study was supported by the Danish Research Council.

Test size variation in *Globigerina bulloides* in response to Quaternary palaeoceanographic changes

SEVERAL different methods have been used to delineate Quaternary palaeoclimatic trends in deep-sea sediments using phenotypic variation in planktonic foraminifera including changes in coiling direction¹, pore concentration², and test surface ultrastructure³. Several workers have observed that test sizes in planktonic foraminifera may differ between different water masses⁴⁻¹⁰ but little attempt has been made to use size variations as palaeoclimatic indices within the Quaternary. The exception is based on size variations in the spherical test of *Orbulina universa* in late Quaternary deep-sea cores from the southern Indian Ocean¹¹. Oscillations in mean diameter of this species closely match late Quaternary palaeoclimatic changes: larger mean diameters occurring during warm episodes. We

Fig. 1 Variation in mean sizes of *G. bulloides* in relation to three palaeoclimatic indices in cores Eltanin 49-19(a) and 48-22(b) from the southern Indian Ocean. The curves are plotted as three-point moving averages. 'Warm' is to the right and 'cool' to the left. Oxygen isotopes and other data for E48-22 are from Williams¹⁴. Chronology plotted on right is based on extrapolation of ages (assuming constant sedimentation rates) from Termination II (128,000 years ago¹⁵) which is at 235 cm in E49-19 and 236 cm in E48-22. ●, Palaeoclimatic principal component; ▲, % sinistral *N. Pachyderma*; ■, oxygen isotope ratios ($\delta^{18}\text{O}$)

report here that changes in mean sizes of *Globigerina bulloides* can also be used as a palaeoclimatic index in the late Quaternary.

We have examined mean size oscillations of *G. bulloides* in three late Quaternary cores from sub-Antarctic waters of the southern Indian Ocean¹² (Table 1). The results from two of the cores are presented here. The third core examined (E45-74) shows conspicuous evidence of calcium carbonate dissolution, and the data revealed no meaningful relationships between size parameters and climatic history. Previously⁸ we have shown that in surface sediments of the southern Indian Ocean, *G. bulloides* increases in mean size with decreasing surface-water temperature, and we wished to test if this trend could be usefully applied to down-core palaeoclimatic studies. The mean size oscillations were compared in both cores with palaeoclimatic curves established from principal component analyses of abundance data of planktonic foraminifera¹³ and frequency changes in coiling proportions of *Neogloboquadrina pachyderma*, and in E48-22 also with a curve based on $^{18}\text{O}/^{16}\text{O}$ ratios.

In core E49-19 from the central sub-Antarctic, the mean size oscillations of *G. bulloides* are very similar in period and amplitude to the palaeoclimatic curves (Fig. 1) indicating a strong

Table 1 Data for Eltanin cores used in the study

Core	Latitude (S)	Longitude (E)	Water depth (m)	Core length (cm)	Age of sequence (kyr)
E48-22	39°53.7'	85°24.6'	3,380	680	370
E49-19	43°53.2'	90°06.0'	3,036	550	300

palaeoclimatic control of the mean size variation. A cross-correlation coefficient of 0.63 ($P < 0.1\%$) indicates that the curves are statistically significantly correlated. Mean sizes are larger during cool episodes and smaller during warm episodes; this pattern therefore agrees with the distribution in surface sediments⁸. Thus, latitudinal shifts in water masses during the late Quaternary created latitudinal displacements of isopleths of mean sizes of *G. bulloides*.

In core E48-22 from the Subtropical Convergence, there are also strong correlations among the mean size curve of *G. bulloides* and the palaeoclimatic indices (Fig. 1). However, in contrast to E49-19, the mean size curve is not exactly in phase with, but is slightly off-set from the other curves. Cross-correlation analyses indicate that it is off-set from the variations in coiling ratios of *N. pachyderma* and oxygen isotopic ratios by 10 cm (to ~5,500 yr) and from the palaeoclimatic principal component by 40 cm (to ~22,000 yr). These differences do not, however, impair the almost perfect correlation between mean sizes and climatic history.

Palaeotemperatures have been estimated for E49-19 and E48-22 using the following palaeotemperature equation established from the mean size variation in *G. bulloides* in surface sediments⁸:

$$\text{Temperature (annual-average surface-water in } ^\circ\text{C)} = -0.1184 (\text{mean width of } G. \text{ bulloides in } \mu\text{m}) + 45.06.$$

The calculations show that surface-water temperatures ranged between about $3^\circ\text{C} \pm 1^\circ\text{C}$ and $10^\circ\text{C} \pm 1^\circ\text{C}$ at the site of E49-19 (central subantarctic) and between about $9^\circ\text{C} \pm 1^\circ\text{C}$ and $16^\circ\text{C} \pm 1^\circ\text{C}$ at the site of E48-22 (Subtropical Convergence). Our estimates for E48-22 agree closely with the temperature range of 6°C to 15°C calculated previously for this core using different parameters¹⁴.

We have therefore shown that mean size of *G. bulloides* in the late Quaternary of the subantarctic is strongly related to palaeoclimatic trends, and hence this parameter represents a potentially valuable new tool for palaeoclimatic analysis in this area.

Genetic differentiation during speciation

SPECIATION theory is still largely descriptive. How many and what kind of genes are implicated in speciation is a central unresolved problem of evolutionary biology^{1,2}. Does speciation require major genomic changes³⁻⁵ or may minor ones suffice^{1,6-9}? Similarly, does speciation depend on structural or on regulatory genes¹⁰? We have investigated these questions with reference to the actively speciating fossorial mole rats of the *Spalax ehrenbergi* complex in Israel, which comprises four morphologically indistinguishable chromosome forms ($2n = 52, 54, 58, 60$)¹¹ adapted in that order to increasing aridity¹². Narrow hybrid zones between karyotypes¹³ and mate selection¹⁴ (through olfaction¹⁵, vocalisation¹⁶ and aggression¹⁷) suggest that the recently¹⁸ formed species represent progressive stages of final speciation¹³. Genic diversity proved low, and genic similarity between karyotypes very high, in the previous test based on 17 gene loci of tissue proteins⁸. The test of eight additional loci of blood proteins, which is reported here, reinforces earlier conclusions and sheds light on the allozyme-environment association and on the amount of genetic differentiation during speciation.

In the previous study⁸, 383 adult mole rats comprising all four karyotypes were tested for 17 gene loci. In the study reported here blood samples of 499 specimens, collected during 1969-1971 from 21 populations of the four karyotypes, were tested for eight gene loci, six in the serum (haptoglobin, *Hp*; transferrin, *Tf*; albumin, *Alb*; slow α_2 globulin (*Gl*); esterases, two scorable loci, *Est-1* and *Est-4*) and two in the haemolysate (haemoglobin, *Hb*, and a non-haemoglobin erythrocyte, *Prot-1*). Routine vertical starch gel electrophoresis was conducted on the separated blood samples. Details of collecting sites and electrophoretic methods and results are available from us. Of the eight loci examined, six (*Hp*, *Gl*, *Alb*, *Est-1*, *Hb* and *Prot-1*) were monomorphic and fixed for the same allele in all 21 populations tested. Only two loci, *Est-4* and *Tf* were polymorphic, with three segregating alleles in each. Transferrin is the only locus, both of the blood and tissue proteins, which displays almost complete alternative fixation: $2n = 54$ is nearly fixed for Tf^a , whereas $2n = 52, 58$ and 60 are either fixed or nearly so for Tf^b ; the rare allele, Tf^c , appears only in $2n = 60$. Mean genetic indices for the *S. ehrenbergi* complex and for $2n = 52, 54, 58$ and 60 , respectively, are: *A* (mean number of alleles per locus) = mean 1.25 (1.16, 1.28, 1.20, 1.36); *P* (mean proportion of polymorphic loci per karyotype; criterion for $P 1\%$) = mean 0.20 (0.12, 0.24, 0.16, 0.28), and *H* (mean proportion of loci heterozygous per individual) = mean 0.039 (0.035, 0.016, 0.037, 0.069). Genetic identity, I^{19} , between the four karyotypes, is remarkably high (mean 0.966, range, 0.931-0.988).

The results support the hypothesis that habitat specialists display significantly lower genic variation than habitat generalists²⁰. Mole rats, like most fossorial mammals⁹, are habitat specialists living apparently in a relatively predictable environment which presumably selects for homozygosity (homoselection), though exceptions exist²¹. The evidence negates genetic drift due to small population effects, inbreeding in relatively semi-isolated populations, or the time hypothesis²² as explanatory models. First, the genetic pattern is characterised by general uniformity of alleles at 24 out of 25 loci in 21 populations across the range of the four abundant karyotypes. Second, *H* is apparently not correlated with time. Evolutionary divergence time for the *S. ehrenbergi* complex, deduced from electrophoretic data²³, is within the last $250,000 \pm 20,000$ yr, in accord with the hybrid zone¹³ and fossil²⁴ evidences. Yet $2n = 60$, presumably the last derivative of speciation 75,000 yr ago, has the highest *H*, not the lowest as expected by the time divergence hypothesis²². Heterozygosity seems to correlate with spatial environmental heterogeneity. The largest range, that of $2n = 60$ (see map in ref. 11), is also the most variable

spatiotemporally in terms of ecological heterogeneity and uncertainty, extending in both Mediterranean and arid environments.

Concerning speciation theory, the *Spalax ehrenbergi* complex represents a remarkable case of speciation with relatively few genomic changes. The nature and extent of hybridisation in *S. ehrenbergi*¹³ reinforces the hypothesis that the chromosome forms are young, closely related species at final stages of speciation. A growing body of evidence from newly formed unrelated plant and animal species²⁵ suggests that the essence of speciation, that is the development of pre- and/or postmating reproductive isolation *per se* may occur with little genomic change, either genic or chromosomal. In many cases the apparent genetic distance between species is the result of post-speciation evolutionary divergence. In the fossorial rodent complexes of *Thomomys talpoides*⁶ and *S. ehrenbergi*, where all stages of evolutionary divergence from large to zero gene flow between diverging populations are known, further development of ethological isolating mechanisms based on the few chromosomal rearrangements which initiated the reproductive isolation have been accomplished without many allelic changes. This pattern is also known in other species²⁵, including some parasites whose speciation involves few changes in either structural or regulatory genes, and also rarely involves chromosome rearrangements². The hypothesis that regulatory rather than structural genes are implicated in speciation¹⁰ is yet to be tested. Until tests of regulatory genes become available it seems plausible to assume that speciation may occur with relatively little genetic change.

Species vary in kind in accord with different strategies of evolutionary adaptations and speciation patterns. Reproductive isolation may either follow or precede the genic or chromosomal divergence of gene pools²⁶, and so speciation may be associated with either major or minor alterations in structural and/or regulatory genes, as well as with chromosomal evolution. The extent of genetic differentiation depends on various correlated and interacting factors, including the taxon, mode and rate of speciation; population and migration size and structure; breeding and mating system; reproductive strategy, chromosomal rearrangements and polyploidy, and the ecological selection structures. To become both predictive and falsifiable, speciation theory must be based on critical multifactorial tests incorporating the genetic system, ecological regime and historical patterns in actively speciating populations.

Limit of single vision in stereopsis depends on contour sharpness

OUR two eyes see slightly different images of the world, and this enables us to estimate the position of objects in depth. When we look at a fixed point in space we can correctly judge the distance of an object that is in front of, or behind this point by the amount of disparity of its retinal images. Our brain combines these disparate images in such a way that we can see the object as single within a certain limit of disparity. This limit is called Panum's fusional area; for fine-line targets the disparity limits are found to be ± 7 min arc for central (foveal) vision, and larger for peripheral vision (for review see ref. 1). However, Fender and Julesz² demonstrated that fusion may be extended beyond Panum's area when random-dot stereograms are used. Experiments reported here demonstrate that Panum's area also increases for stimuli with blurred contours, that is, for contours containing lower spatial frequencies.

Figure 1a shows three gratings of sinusoidal luminance profile; the adjacent gratings are in antiphase, that is, each light bar in one grating corresponds to a dark bar in the other. Each grating is surrounded by a contour and provided with short vertical lines at the top and bottom to facilitate fusion. The first

task of the observer is to fuse the top lines of the top gratings (the bottom left grating and the rest of the page should be covered). Fusion of the top lines is easier when a cardboard partition is put between the gratings, so that each eye views only one grating. It will be seen that after the short lines and the rectangular outline are fused, both the gratings can also be fused (although at first the light bars seem superimposed on dark bars and vice versa). They are seen as a single grating either closer or further away than the short lines (as observed previously by Blakemore and Hague³). The criterion of appropriate fusion is that the top short lines are seen pointing between the light and dark bars of the grating for observers with good binocular vision. (If an observer has one eye strongly dominant, this eye will determine the perceived position of the short line). This fusion is not affected by viewing and fusion of the bottom instead of the top short lines, except that now the short lines are seen in the middle of a light or dark bar of the grating. In both viewing conditions, single vision and stereopsis are easily established over a wide range of viewing distances and this finding was confirmed on 15 observers with normal binocular vision. This indicates that the disparity range of single vision is at least as large as the width of one bar (or a half-cycle of the grating), which at a viewing distance of 10 cm is about 4°.

Now cover the right grating, uncover the left bottom grating and rotate the figure by 90° so that two horizontal gratings (in antiphase) can be viewed by left and right eyes, respectively. It will be seen that now fusion becomes difficult and even if it occurs (most often by suppressing one eye) it does not produce stereopsis.

The next demonstration is concerned with the square-wave gratings (Fig. 1b) in antiphase. Such patterns, with sharply outlined contours, are known to be interpreted in the visual system by detection of their edges⁴⁻⁷, which contain higher spatial harmonics⁸.

First try to fuse the top short lines using the same method as when viewing Fig. 1a. Now, however, a simultaneous fusion of the top short lines and the gratings is very difficult, as the sharp edges of the gratings in antiphase seem to produce rivalry, otherwise the edges are not seen as sharply. In spite of this, all 15 observers saw the square wave grating in depth, either closer or

Fig. 1 Demonstration of depth perception with and without single vision of contours. *a*, Sinusoidal gratings in antiphase can easily be fused, after fusing the short line in the top two figures (all other figures should be covered by a white sheet of paper). Observers finding this task difficult should put a piece of cardboard, in the sagittal plane, between their eyes and the two gratings, so that the left and right eyes view only left and right gratings, respectively; start viewing the figure at a distance of 20-30 cm and then gradually reduce the viewing distance. Note that the vertical gratings are fused and perceived at a different depth from that of the short fixation lines over a wide range of distances (down to < 10 cm) and that the gratings do not produce the depth effect if the whole display is rotated through 90°. *b*, Square-wave gratings in antiphase can be fused initially only at a distance over 30 cm, but gradually also at smaller distances. The square-wave grating is then seen in depth relative to the short lines, but the sharp edges of the grating become double or unclear at distances < 15 cm. It is important that the observer sees the gratings in focus with both eyes (otherwise, defocused gratings lose their sharp luminance profile and become similar to the sine gratings). Viewing the gratings horizontally produces only binocular rivalry. *c*, Fusion of single bars of either cosinusoidal or sharp (square) profile is equally easy when looking at the gaps between the short lines in the middle of the figure: both bars are seen as single and in depth. However, the sharp edges of the bars are seen either double or unclear when the observer looks at the bottom short lines at viewing distances < ~10 cm.

farther away than the short lines, and 12 of them reported rivalry at the same time. Only three observers (all of whom had a strongly dominant eye) reported seeing sharp edges without any rivalry, possibly by suppressing the rival contour produced by the nondominant eye. This suggests that the nondominant eye may contribute to stereopsis without producing a rival double image.

Although the periodicity of the patterns in Fig. 1a and b helps in seeing them in depth (as several contours have similar disparity⁹), it is not a necessary condition for this phenomenon. Figure 1c shows two pairs of single bars corresponding to those in Fig. 1a and b. Now, however, for comparison the sharp bars (bottom) and the 'blurred' bars with a sinusoidal profile (top) are presented simultaneously in the same disparity with respect to the short lines. Some observers find it difficult to fuse the short lines between the bars, but after several attempts it is usually possible to perceive the bars as being closer than the short lines (if the left and right eyes look at the left and right lines, respectively). The sharp edges of the square-wave bars, however, are seen as double.

All the phenomena shown in Fig. 1 suggest that objects with sharply outlined contours and patterns with gradual luminance gradients have different ranges of disparities over which they are seen as single, or at least not seen as rival double images. In other words, the range of single vision in stereopsis is inversely related to the spatial frequencies present in the pattern, as though there were many Panum's areas instead of one determined with fine lines.

Neurophysiologists¹⁰⁻¹² have noted that units with small receptive fields, representing central vision, often have a narrower range of disparities than units with large receptive fields representing peripheral vision. However, the phenomena reported here are concerned mainly with central vision (note that the bars in Fig. 1c may be made shorter without affecting the percept). Graham, Robson and Nachmias¹³ have demonstrated that central vision has a range of mechanisms tuned to different sizes (or different spatial frequencies). Also, Maffei and Fiorentini¹⁴ noted that cortical cells subserving each part of the visual field are tuned to a range of sizes (spatial frequencies). Although specific neurophysiological investigations relating the range of disparities to the receptive field size in the same part of central vision have not yet been published, some experiments hint that such a relationship may exist. Simple cells in the cat visual cortex responsive to low spatial frequencies tolerate a greater lateral misalignment of line stimuli presented dichoptically than the cells responsive to higher spatial frequencies (D. J. Tolhurst, J. D. Thompson and C. Blakemore, personal communication).

Other psychophysical experiments also point to different binocular processing of sinusoidal and square-wave gratings in antiphase (J.J.K. and I. Wood, in preparation). The binocular contrast thresholds for the detection of sinusoidal gratings were the same whether the gratings were in-phase (identical) or in antiphase for the two eyes. However the thresholds for binocular viewing of square-wave gratings were higher when the gratings were in antiphase as compared with the thresholds for the in-phase presentation. This finding may be of clinical importance, for as the sinusoidal gratings do not produce rivalry irrespective of their phase they could be used for exercising binocular vision in patients with squint.

I thank Drs P. O. Bishop, C. Blakemore, W. N. Charman, D. J. Tolhurst and T. R. Vidyasagar for discussions.

Telephoto lens system of falconiform eyes

VISUAL ACUITY in falconiform birds has been shown to be higher than man. For instance, vultures with eyes similar in size to those of man have a grating detectability of about twice the spatial frequency of man¹. This is consistent with measured image quality in an eagle eye similar in size to the human eye². Recently a falcon (*Falco sparverius*) has been shown to have a grating detectability 2.6 greater than that of man³. Although the image quality of these falconiform eyes is at least twice as good as man, their minimum intercone spacing is only slightly less than in the human retina. Unless the ratio of focal length to the axial eye length of these birds greatly exceeds that in man, falconiform eyes, unlike man, would be unable to resolve their best retinal image quality. We show here that the presence of a spherical depression in the deep fovea of falconiforms may act like the negative lens component in a telephoto lens system or opera glass. The focal length of the birds' dioptries can then in theory exceed the axial length of the eye, thus providing the relatively large images necessary for more complete image reconstruction (high resolving power) in a localised region of the retina.

The anatomical resolving power of an eye is set by the image size and by the receptor grain. The image size is specified by the focal length, f , while the receptor grain is specified by the centre-to-centre spacing of foveal cone, d . It is convenient to define an anatomical resolving power, RP , as the reciprocal of the angular separation between cone centres:

$$RP = f/d \quad (1)$$

In order to determine precisely the intercone distance, d , we made photoreceptor counts by light microscopy on fresh material and by light and electron microscopy on fixed material in the deep foveas of numerous birds ranging from large eagles to small falcons and, for comparison, in human foveas⁴. In all situations shrinkage was carefully monitored and corrected for, and only the most central region of the fovea was examined. In all falconiforms studied $d \approx 2 \mu\text{m}$, independent of their eye size, while $d \approx 3 \mu\text{m}$ in man. In man, focal length $f \approx 17 \text{ mm}$ (ref. 5) while in falconiforms f (believed to be accurately estimated from the curvature of the retina^{6,7}) measured in all our birds was found to be $f \approx 0.65L$, where L is the axial eye length. Using equation (1), the anatomical resolving power of falconiforms with eyes the same size as man ($L \approx 24 \text{ mm}$) is only 1.38 times that of man. If the resolving power of these birds is to equal twice that of man, then f must equal 22.6 mm or 1.45 times that measured from the retinal curvature. We next show that this amount of image magnification is in fact consistent with the optical function of the bottom of the foveal pit.

Falconiforms are well known to have a deep nasal fovea^{8,9}, see for example, Fig. 1, where Fig. 1b shows the deep fovea of the red-backed hawk, *Buteo*, which also has a 'man-sized' eye. We call attention here not to the steep sides of the fovea^{8,10}, but rather to the fact that the bottommost portion of the pit is a well formed hemisphere. Our hypothesis is that this concave portion of the foveal pit (labelled by the arrow in Fig. 1b) functions as a negative lens which, together with the positive power of the cornea and lens, acts like the telephoto optical system of Fig. 2. This system has an effectively long focal length which, in

Fig. 1 *a*, Schematic of an avian eye viewed ventrally, illustrating the relative position of the deep or nasal fovea (DF). The figure is adapted from the hawk *Buteo latissimus*¹⁴. *W*, the head width, approximately equals twice the axial eye length *L*. *b*, Unstained 10- μ m thick section of glutaraldehyde-fixed retina of red-backed hawk in region of deep fovea. Section photographed using interference contrast. Increasing darkness indicates higher refractive index. Arrow indicates concave region of foveal pit which we hypothesise may function as a diverging optical element to project magnified image on receptors at centre of fovea. Note that *n* is uniform between internal and external limiting membranes outside of fovea on extreme right of figure. Dark densities sclerad to ELM are the result of pigment and do not necessarily relate to *n*. ELM, external limiting membrane; OD, oil droplets; OS, outer segments; PE, pigment epithelium. Scale bar, 100 μ m.

theory¹¹, can even exceed the physical length of the eye. Walls⁸, ignoring the bottommost portion of the pit, suggested that the steep sides of the foveal pit magnifies the image, but Pumphrey¹⁰ showed that instead they cause distortion.

Thus, from Fig. 2 the effective focal length of the bird eye is given by mf , where m is the magnification¹¹ of the foveal pit, defined in the legend of Fig. 2*b*, and f is the focal length used in equation (1). Therefore, from equation (1), the resolving power of falconiforms is mf/d . The magnification m increases the smaller the radius of curvature R of the concave pit and/or the greater the distance s of the bottom of the pit from the photoreceptors. From our above discussion, m must equal about 1.45 for the man-sized falconiform eye to have twice the resolving power of man.

Using the deep fovea of the red-backed hawk in Fig. 1*b* as an example, with $s = 110 \mu\text{m}$ and $R = 6 \mu\text{m}$, then the refractive index n_r of the deep fovea must equal 1.369 if m is to be 1.45. This result is found from the equation in the legend of Fig. 2*b* assuming the refractive index of the vitreous humor¹² is the same as man and cat⁵, that is, $n_c = 1.336$. There are several convincing reasons why n_r should equal or exceed 1.369. First, the vitreal surface of the foveal pit is formed by Müller cells only. From our electron micrographs, these Müller cells are seen to be exclusively and densely packed with microfilaments. Similar protein, for example, collagen in the cornea, has a refractive index¹² $n_r \approx 1.55$. Second, interference microscopy of the red-backed hawk fovea, (Fig. 1*b*) indicates an n_r similar to that of the cone outer segments¹³ for which $n_r \approx 1.4$. Since the regions of highest n in Fig. 1*b* are shown as the darker areas, the region below the pit has a nonuniform refractive index. Thus, Fig. 2 represents only a crude model of the optics. We emphasise that the high refractive index region surrounding the spherical pit in Fig. 1*b* is absent in extrafoveal regions and in all primate foveas and less apparent in the shallow foveas of falconiforms. Third, measurement of interference fringe displacement in the deep fovea of a glutaraldehyde fixed, Spurr's media embedded specimen (Fig. 1*b*) indicates a minimum value of 1.379 for the refractive index of both the pit and sides of the deep fovea. However, this value is a lower bound because we have not adjusted for the fact that the high n Spurr's medium infiltrates the denser tissue more than the less dense tissue. The measured n value is consistent also with the intensity of the foveal reflex

believed equal to that of myelinated nerve fibres of the optic disk¹⁴. Thus, the very high refractive index below the spherical pit and its radius of curvature are consistent with the pit functioning as a negative element in a telephoto lens system.

The deep fovea may also act as a focus indicator; however, both the nail polish and the ray models used to test this hypothesis¹⁵ were not scaled to give the correct magnification factor as determined by our interference microscopy and anatomical measurements (L. Harkness, personal communication). When appropriately scaled, we have observed the magnification predicted by the telephoto lens model and furthermore, the entire 'retinal' image is in focus in the same plane that magnification occurs.

There are distinct disadvantages associated with the telephoto lens system described above, including a narrow field of view for high resolving power and susceptibility to aberrations caused by the steep sides of the fovea. Why is it then that the avian eye did

Fig. 2 Schematic of the telephoto lens. *a*, Classical design. *b*, Equivalent system of avian eye where the negative lens is replaced by a spherical (concave) surface. The magnification of the system,

$$m = 1 + \frac{s}{R} \left(\frac{n_r - n_c}{n_c} \right)$$

where n_r and n_c are the refractive indexes of the medium to the right and left of the spherical surface respectively, R the radius of curvature of the surface and s the distance from the apex of the spherical surface to the image plane. The position of the oil droplets is taken as the image plane in Fig. 1*b*.

not simply have a higher cone density, avoiding these difficulties? The answer may be found in the constraints imposed by the wave nature of light. Because of frustrated total internal reflection¹¹, photons within one outer segment have a probability of crossing over into neighbouring outer segments. This optical 'cross talk'¹⁶ increases the more densely packed the cones become, manifesting itself by an increased reduction in contrast sensitivity. If high resolving power is the animals' primary objective, the deep fovea, acting as the magnifier of a telephoto lens, may be a strategy superior to a fine receptor grain.

Although our arguments have been applied mainly to falconiforms with man-sized eyes, they should hold more generally. In all of the falconiforms we have studied, the focal length f of equation (1) is directly proportional to axial eye length L while the minimum inter-cone spacing d and magnification m due to the deep fovea are independent of eye length. Consequently the resolving power, RP , of these birds should be directly proportional to L or equivalently to the animals' head width W of Fig. 1a. Our finding that the birds' pupil diameter, as measured in bright natural conditions, is directly proportional to L is also consistent with the RP being directly proportional to L . This follows assuming, as in man¹⁷, that the birds' best image quality (minimum line spread) is nearly diffraction limited and occurs at the smaller (bright light) pupil diameters.

Finally, recall that grating detectability provides only a limited assessment of bird visual superiority. Alternatively consider a distant point object. The most crucial determinate of detection is then maximum image brightness which also equals the two-dimensional polar area under the modulation transfer function of the optics¹¹. From the modulation transfer function for the optics^{2,17}, we calculate that the man-sized eagle eye can, in theory, detect a distant point object at a distance 3 to 8 times greater than man. This ratio is nearer to 8 when the object is significantly brighter than its surround, and ~ 3 when the object brightness is equal or less than its surround. Such superior visual acuity is in better agreement with the reported observations¹⁸ than the value of twice that of man found from grating detection¹.

Thus man-sized falconiform eyes have an image quality at least twice as good as man², yet their minimum inter-cone spacing is only slightly less than man⁴. Nevertheless, our anatomical findings and refractive index measurements are consistent with the hypothesis that the spherical portion of the deep fovea acts like the negative lens component in a telephoto lens system. The focal length of the dioptrics may then be sufficiently extended for the bird to resolve its superior retinal image in a localised region.

We thank Jerry Olsen of CSIRO for procuring and handling the birds. Part of this paper is abstracted elsewhere¹⁹. This work was supported in part by USPHS grants EY00089, EY00785 (W.H.M.) and by a John Simon Guggenheim Foundation Fellowship (A.W.S.).

Cyclophosphamide delays 3-methylcholanthrene sarcoma induction in mice

THERE is increasing evidence to show that suppressor T lymphocytes facilitate the growth of neoplasms that have tumour-specific transplantation antigens¹⁻⁶. Studies on suppressor cell activity with respect to various non-tumour antigens have shown that treatment of mice with cyclophosphamide depresses suppressor cell-mediated mechanisms to a greater extent than the effector arm of the immune response⁷⁻⁹, provided the proper dose and timing for drug administration was used. Based on these observations we speculated that treatment of mice with cyclophosphamide during the latency period of tumour induction might prevent (or at least delay) the appearance of primary tumours. We show here that this hypothesis is correct. In BALB/c mice given 3-methylcholanthrene (MCA) and injected with cyclophosphamide (2 mg per mouse) every 10 days, the appearance of primary sarcomas was delayed. Because the effects were striking, and were obtained with one of the drugs most commonly used in cancer chemotherapy, we decided to report the data. We are, however, aware that explanations for the drug effect other than interference with suppressor cell activity are equally possible, including a direct effect of the drug on tumour cells.

BALB/c mice were bred by brother to sister mating at the Fred Hutchinson Cancer Research Center. Female mice, 6-8 weeks old, were randomised into six experimental groups, each group comprising 50 mice except group 6 which had 45 mice. All mice received an intramuscular injection into each thigh of 0.1 mg MCA dissolved in triolein. The day of MCA injection is referred to as day 1 of the experiment. Two groups (1 and 4) were injected subcutaneously on 4 occasions (days -10, 20, 50, 80) with 10^6 heavily irradiated cells per mouse from tumour 1423. This tumour is an MuLV antigen negative MCA-induced BALB/c sarcoma; these tumour cells were pre-irradiated with 15,000 rad *in vitro*⁶. The tumour cells were injected to determine whether any immunisation to putative common TSTA could be obtained. Two other groups (2 and 5) were similarly injected with cells from normal BALB/c kidneys, while the remaining two groups (3 and 6) received phosphate-buffered saline (PBS) only. Cyclophosphamide was injected intraperitoneally at 10-day intervals in a dose of 2 mg per mouse (corresponding to approximately 100 mg per kg body weight at the onset of the experiment), starting 13 days before MCA and continuing throughout the experiment, in groups 4, 5 and 6. This dose of cyclophosphamide was chosen on the basis of experiments performed in an allograft system, which examined suppressor cell activity controlling the cell-mediated allograft response in BALB/c mice¹⁰. The time schedule was based on the evidence that suppressor T cells have a half life of less than 4 weeks¹¹. Groups 1, 2 and 3 were injected with PBS instead of cyclophosphamide. The previously ear-tagged mice were observed at weekly intervals for tumour development; the treatment

* 2 mg cyclophosphamide per mouse intraperitoneally 13 d before MCA and at 10 d intervals afterwards.
† 10⁶ cells irradiated with 15,000 rad *in vitro*, were injected subcutaneously 10 d before MCA and at 30 d intervals on three more occasions.
‡ Data pooled from mice with unilateral or bilateral tumours. All groups comprised 50 mice except group 6, in which there were 45 mice. Mice were inoculated with 0.1 mg MCA into each thigh on day 1.

of the mice was unknown to the observer. The appearance and growth of tumours in each thigh was recorded. Statistical significance was calculated by χ^2 analysis.

As shown in Table 1, groups receiving cyclophosphamide developed tumours much more slowly than did untreated groups. At all times of observation except the first (84 days after MCA), the differences were statistically significant at the *P* < 0.001 level; 84 days after MCA, the *P* value was <0.02. At the time of writing, 142 days after injection of MCA, all but one of the mice in the controls had at least one tumour, whereas 40% of the mice in the cyclophosphamide treated group remained tumour free. However, the major effect was probably a delay of tumour appearance rather than a prevention of tumour induction, since the appearance of new tumours in the drug treated group has not levelled off. The cyclophosphamide treated mice have shown no signs of sickness and have increased in weight at the same rate as mice not receiving the drug. The few non-tumour related deaths observed have been no more frequent in the drug treated groups (Table 1).

There was no difference in tumour induction between groups which were immunised with tumour 1423, or injected with normal kidney or PBS. Thus, there was no evidence for any immunisation to antigens shared by the 1423 sarcoma and primary MCA sarcomas. This observation agrees with previously reported failures to immunise against MCA carcinogenesis by giving MCA tumours during the latency period¹², but does not exclude that immunisation with other tumours, either induced by MCA or in another way, may be effective¹³. The failure of 1423 sarcoma cells to immunise against any putative common TSTA was not altered by cyclophosphamide treatment (group 4).

The delayed tumour appearance in groups that received cyclophosphamide is consistent with the hypothesis that cyclophosphamide inhibits tumour growth by interfering with either a suppressor cell mechanism or an immunostimulatory mechanism of the type described by Prehn¹⁴. However, it is equally consistent with a non-immunological interpretation. Cyclophosphamide may, for example, have destroyed neoplastic cells as they developed or it may have interfered with carcinogenesis. That we do not know the mechanisms of the drug effect in this system should not, however, detract from the fact that a very substantial delay in primary tumour induction was obtained, using a protocol which has few apparent side effects. Work in progress in our laboratory, using cyclophosphamide treatment in conjunction with adoptive transfer of lymphoid cell populations containing suppressor cells, should

determine whether the drug has any effect on suppressor cells during chemical carcinogenesis.

**Neoplastic transformation of human
diploid cells *in vitro*
after chemical carcinogen treatment**

ALTHOUGH many unsuccessful attempts have been made to transform normal human cells to the neoplastic state¹⁻⁴, the putative transformations reported have been primarily with cell lines^{5,6} derived from xeroderma pigmentosum biopsies or osteosarcoma tumour tissues⁷⁻⁹. Recently, cells from a skin biopsy taken from the lip of an adult female were reported to be transformed by 4-nitroquinoline oxide and *N*-methyl-*N*¹-nitronitrosoguanidine¹⁰ (MNNG). We now report that primary or low passage cells *in vitro* from various human foreskin cell populations can be neoplastically transformed *in vitro* by six

different chemical carcinogens. A close correlation between growth in soft agar and tumour formation in nude mice was obtained.

Randomly proliferating human cell populations have an extremely rapid DNA repair system that is exceedingly proficient and error free^{11,12}, as over 90% of the damage caused by the chemical carcinogen is repaired within 4–10 h (ref. 13). When normal diploid human cell populations were exposed to known chemical carcinogens, transitory abnormal cellular, morphological and culture characteristics, such as polygonal morphology, criss-cross orientation of the fibroblast cells and loss of density-dependent inhibition were expressed. We have not yet been able to regularly demonstrate transformation of randomly proliferating cell populations prepared from different skin tissue samples. However, reproducible transformation occurred when scheduled DNA synthesis was altered and proliferation of the normal (unaffected) portion of the cell population was impaired. To obtain transformation the normal cell populations were blocked in G₁/S interphase, then

treatment with PMA, insulin, anthralin or oestradiol. The range for cells in S was 67–95% with a mean value of 90% of the cells going through S phase of the cell cycle for a population of 1.5×10^6 cells in these culture conditions. Carcinogen stock solutions had been prepared by dissolving the chemical in acetone and diluting with 100 ml of CM immediately before use. The concentrations used were made by further dilutions of the stock solutions with CM. After the treatment period, the cell cultures were washed three times with CM and immediately sub-passaged 1:2 into CM containing 8× nonessential amino acids (MEM, Flow) and 2× vitamins. When the cell populations were 75% confluent, the cultures were serially passaged 1:10. This ratio of subpassaging the cultures was continued for 20 population doublings (PDL). The saturation density of the transformed cell populations examined always exceeded the density of the normal untreated cell populations (Table 1).

After 20 PDL, 50,000 cells were seeded into 2 ml of 0.35% agar or 1.0% methylcellulose (6,000 c.p.s.) supplemented with

Table 1 Population density and colony-formation capability in 0.5% agar of control and carcinogen treated cell populations

Chemical carcinogen ($\mu\text{g ml}^{-1}$)	No. of treated populations*	Cell density† ($\times 10^6$ per 75 cm^2)	No. that grow in soft agar‡	Frequency of colony formation in agar
0	—	1.7	—	—
PS (5.0)	7	4.0	7	$1:10^{3.5}$
β -PL (13.0)	4	9.0	4	$1:10^{3.7}$
Af-B ₁ (10.0)	7	4.5	7	$1:10^4$
MNNG (0.1)	8	3.0	6	$1:10^5$
4-NQO (0.002)	10	6.0	7	$1:10^6$
EMS (10.0)	7	8.0	5	$1:10^{3.5}$

The following were added at PDL 1.5: PS, β -PL, aflatoxin B₁ (Af-B₁), MNNG, ethyl methane sulphonate (EMS), 4-nitroquinoline-1-oxide (4-NQO).

* Primaries were derived from 10 different foreskin samples per treatment and cultures of each were used with chemical carcinogens.

† Mean cell population densities (M -cell density $\times 10^6$ per 75 cm^2) were determined 7 d after 1:4 split. These values represent 10 different experiments.

‡ Fifty-thousand cells were seeded into 2 ml of 0.35% agar over a 5 ml 2% base in 25 cm^2 wells. These cultures were incubated at 37 °C in a 4% CO₂-enriched air atmosphere and re-fed on day 7 with 0.5 ml of medium-supplemented soft agar. The base agar medium was supplemented with RPMI 1629 and the soft agar was supplemented with Lo-Cal medium (Biolabs). Colonies, >100 cells per colony, were counted 9 d after seeding.

released and treated with the appropriate carcinogen during the S phase of the cell cycle. After carcinogen treatment proliferation of the unaffected cell population was purposely inhibited. Moreover, if morphologically altered colonies were selectively removed and grown in conditions that restricted proliferation of unaffected cells in mass culture, there was an increase in the growth of the abnormal cell populations.

Randomly proliferating cell populations obtained from 10 foreskin tissues dispersed with collagenase¹⁴ were sub-passaged in complete medium (CM) composed of minimum essential medium–25 mM HEPES (Gibco) at pH 7.2 supplemented with 10% fetal bovine serum (FBS) (Rehatuin), 1 mM sodium pyruvate, 2 mM glutamine, 0.2% sodium bicarbonate, 5.0 $\mu\text{g ml}^{-1}$ gentamycin, in an atmosphere of 4.0% CO₂ enriched air at 37 °C. Preconfluent (70–80%) logarithmically growing cultures were transferred to Dulbecco's modified Eagle's medium (Biolabs) lacking arginine and glutamine, at pH 7.2 supplemented with 10% dialysed FBS to decrease cell multiplication. After 24 h, the amino acid-deficient medium was replaced with CM to which either 0.5 IU of insulin or 1 $\mu\text{g ml}^{-1}$ 17- β -oestradiol, anthralin, or phorbolmyristate-acetate (PMA) had been added. Ten hours later, chemical carcinogen in CM was added with either PMA, anthralin, insulin or oestradiol. This time coincided with the time when the maximum number of cells were in S phase of the cell cycle. Both chemical carcinogen and PMA, anthralin, insulin or oestradiol were removed 12 h later. This time interval coincided with the end of the S phase of the cell cycle (8.3 h). The absolute number of cells in S varied from tissue to tissue and

modified Dulbecco's Lo-Cal growth medium (Biolabs) over a 5 ml 2% base supplemented with RPMI 1629 growth medium–20% FBS. After incubation for 17 d in a 4% CO₂-enriched air environment at 37 °C, colonies formed. Agar-containing cultures were re-fed every 7 d with 0.5 ml of Lo-Cal medium supplemented soft agar. The frequency of colony formation in soft agar ranged from $10^{-3.5}$ to 10^{-6} and for methylcellulose from 10^{-6} to 10^{-7} for the different carcinogen treated cell populations at PDL 20 (Table 1). These colonies were isolated from each semisolid growth medium and seeded into CM containing nonessential amino acids and grown until confluent. When 20,000 cells again were seeded into soft agar, or methylcellulose, the colony frequency approached 100%.

A comparison of the frequency of growth in soft agar, or methylcellulose, indicated that PDL 20, after treatment was discontinued, was a suitable PDL for determining the ability of transformed cell populations to grow in soft agar. Cell populations with a high capacity for growth in soft agar or methylcellulose also grew to relatively higher cell density than normal cultures (Table 1). For example, aflatoxin B₁-treated cell populations at PDL 28 grew in soft agar at $1:10^4$ or methylcellulose, at a frequency of $1:10^{5.4}$ after 17 d. At this PDL the population density in a treated flask was 4.5×10^6 cells per 75 cm^2 after 4 d, while the population density in the control 75 cm^2 flask was 1.7×10^6 cells. At PDL 40 the frequency of growth in soft agar was $1:10^3$ and in methylcellulose it was $1:10^{4.6}$.

After the colonies were removed from the semisolid medium and grown in culture these cells were reseeded into soft agar:

Table 2 Tumour growth in nude mice of same cell lines treated with chemical carcinogens

Cell population	Agar derived cell lines tested	Mice with tumours/mice injected
PS	3	7/11
β -PL	1	3/4
Af-B ₁	3	8/14
MNNG	1	3/5
4-NQO	1	2/4
EMS	1	3/4

At PDL 40–50 the transformed cell populations previously removed from the soft agar were injected into irradiated mice at a cell density of 5×10^6 cells per nude mouse. A 'tumour take' was described as a nodule, 0.5 cm in diameter, that was palpable within 4 weeks after injection. None of the untreated cultures at cell densities of 10^7 cells produced tumours when injected into the mice.

100% of the seeded cell populations formed colonies. A similar response was observed with propane sultone (P.S.), β -propiolactone- or aflatoxin B₁ (Af-B₁)-transformed cell populations, whereas only 25%–70% of the reseeded cell populations, treated with 4-NQO, ethyl methane sulphonate, methyl methane sulphonate, or MNNG, formed colonies in soft agar.

Colonies were removed from the soft agar and serially propagated to a cell density of 10^{6-3} . The ability of these cells to grow in soft agar was correlated with tumour formation in the nude (*nu/nu*) mouse (Table 2). Preliminary chromosome analysis confirmed that all cell lines examined had a human chromosomal constitution with a diploid or near diploid stem line. G-band analysis demonstrated that some lines, despite their normal diploid chromosome number, contained numerical deviations or abnormal chromosomes. C-band analysis revealed other alterations such as pericentric inversions and chromosomes with large areas of heterochromatin or abnormal chromosomes with more than one centromere. These transformed cells were injected into the subscapular region of the *nu/nu* mice previously irradiated with 450 rad (ref. 15). The bleb regressed between 24 and 96 h depending on the size of the inoculum. Subcutaneous tumours appeared in the subscapular areas 18–25 d after injection of the cell mass. After 4–6 weeks, the tumours (0.8–1.5 cm) were surgically removed, part was examined histopathologically and the rest transplanted into other mice. The tumours were composed of multiple vacuolated cell types predominantly a syncytial network with eosinophilic cytoplasm and ovoid basophilic nuclei. There

were also foci of more centrally very vacuolated basophilic staining cells with central or peripheral nuclei (Fig. 1). The presence of these cells composing the foci in the tumour mass is consistent with presence of proliferating exogenous cells producing the tumour mass. The tumours were classified as undifferentiated mesenchymal tumours, and the tumour incidence was recorded (Table 2). To date, all cell lines derived from agar injected into nude mice produce tumours. Tumours have been serially subpassaged $3 \times$ to date. Palpable growths formed in 4 weeks and reexamination of these growths confirmed their mesenchymal origin.

We thank Drs Charles Frith and Stephen Weisbrode for evaluating tumour histopathology and N. Popescu for chromosome analysis. We thank Robert Zimmerman, Jack Berno, Thomas McMichael, Donna Parson and Inge Noyes for technical assistance. This work was supported in part by NCI grant N01-CP-43276.

Resorbing bone is chemotactic for monocytes

MONOCYTES are often found adjacent to bone-resorbing surfaces. Their function at these sites is unknown, although they have been shown *in vitro* to have the ability to resorb bone^{1,2}. There is also strong circumstantial evidence that circulating monocytes are precursors for the major bone-resorbing cell, the osteoclast^{3–7}. The mechanism by which circulating monocytes are attracted to sites of bone remodelling are unknown. We have examined the products of resorbing bone for chemotactic effects on circulating human monocytes and found that organ cultures of resorbing fetal rat long bones produced factors which were chemotactic for human peripheral blood monocytes, but not for neutrophils or lymphocytes. The chemotactic effect of resorbing bones occurred independent of the humoral mediator of bone resorption. The mechanisms by which monocytes are attracted to bone surfaces may be of fundamental importance to our understanding of bone cell dynamics and bone resorption.

The source of bone used in these experiments was the 19-d fetal rat radius and ulna, which had been previously labelled with ⁴⁵Ca as described previously^{8,9}. These bones resorb in organ culture in response to parathyroid hormone (PTH) and other stimulators of bone resorption^{8,9}. Bones were cultured

Fig. 1 A serial section of a tumour formed from proliferating aflatoxin B₁ treated cell populations in the nude mouse. The tumour was excised after 6 weeks in the mouse, fixed in glutaraldehyde and stained with haematoxylin and eosin. This tissue section reveals that tumour vascularisation has taken place. $\times 120$.

Table 1 Chemotactic responses of human monocytes and neutrophils to resorbing bone, using the Boyden chamber technique

Chemotactic sample	Bone resorption* (% ^{45}Ca release)			Monocyte chemotactic activity†		Neutrophil chemotactic activity†
	Expt A	Expt B	Expt C	Expt A	Expt B	Expt C
Media from PTH (400 ng ml $^{-1}$)-treated bones	65 ± 10‡	94 ± 3‡	83 ± 2‡	165 ± 15‡	61 ± 9‡	16 ± 1
Media from paired bones cultured in control media	27 ± 0.3	59 ± 7	33 ± 4	83 ± 6	27 ± 3	19 ± 2
Control media				86 ± 10	41 ± 5	29 ± 2
Control media + PTH (400 ng ml $^{-1}$)				94 ± 13		
Bacterial factor				140 ± 13‡	69 ± 14‡	102 ± 4‡
Leukotactic factor from zymosan-activated serum					118 ± 9‡	116 ± 6‡

Experiments A and B were carried out using polycarbonate filters (pore size 5 μm) and experiment C with cellulose acetate filters (pore size 0.65 μm). Bones were cultured in BGJ medium supplemented with bovine serum albumin (2 mg ml $^{-1}$). In experiments A and B the mononuclear cell concentration added to the upper compartment of the Boyden chambers was 5×10^6 cells ml $^{-1}$. In experiment C, the starting neutrophil concentration was 2.5×10^6 cells ml $^{-1}$. Bovine PTH (400 ng ml $^{-1}$) was provided by G. Auerbach; $1\alpha, 25(\text{OH})_2 \text{D}$ (10^{-8} M) was provided by Hoffman-LaRoche; PGE_2 (10^{-7} M) was from Upjohn.

* Values are means $\pm$ s.e.m. for 4 pairs of bones.

† Chemotactic activity is expressed as the average number of monocytes or neutrophils into the filter per high power field ($\pm$ s.e.m.).

‡ Significantly greater than control media ($P < 0.05$).

for 120 h in BGJ medium (Gibco) supplemented with bovine serum albumin (2 mg ml $^{-1}$) or 5% heat-inactivated fetal calf serum. PTH and other stimulators of bone resorption were added to culture dishes containing two long bones in 0.5 ml medium. Corresponding paired bones from the opposite limb were cultured in control media. Bone resorption was quantified by measuring the percentage of total ^{45}Ca released from the two bones into the medium during the culture period. Media taken from the stimulated and control bones were tested as potential attractants for human monocytes using both the Boyden chamber apparatus¹⁰ and the technique of monocyte chemotaxis under agarose¹¹.

Mononuclear cells were obtained from normal platelet-pheresis donations from the Connecticut Red Cross, Farmington¹. The leukocyte-rich buffy coat was separated from red cells and platelets by adding 5 ml 6% dextran and allowing the red cells to sediment by gravity. The buffy coat contained about 85% lymphocytes and 15% monocytes. Few polymorphonuclear leukocytes were present. The cells were suspended in BGJ medium at a concentration of 2.5×10^6 cells ml $^{-1}$ and added to the upper compartments of modified Boyden chambers¹⁰. The Boyden chambers were incubated in an atmosphere of 5% CO_2 and air at 37 °C for 4 h, after which the filters were removed, fixed, stained with haematoxylin, and examined by light microscopy (250 $\times$ magnification). Two types of Micropore filters were used, polycarbonate filters with uniform diameter linear pores of 5 μm diameter (Nucleopore) and nitrocellulose filters which have convoluted pores of 8 μm diameter (Schleicher and Schuell). Chemotactic activity was expressed as the number of cells which migrated into the filter in six random microscopic fields.

Table 1 shows the relative migration of mononuclear cells from the upper compartment of the Boyden chambers towards media from control or PTH-treated bones in the lower compartment. PTH in maximal doses caused more than 60% bone resorption as indicated by ^{45}Ca release. Media taken from the PTH-resorbed bones clearly attracted mononuclear cells into the membrane filters compared with media taken from the control bones and control media (Table 1). This effect was not due to PTH because when PTH-containing media which had not been cultured with bone was added to the lower compartment, there was no chemotactic effect (Table 1). In another experiment, PTH was added to media taken from bones cultured in control media, but again there was no increased chemotactic effect compared with control media alone, or control media cultured with bones for 120 h (data not shown).

The chemotactic activity of the resorbed bones was similar to that of two known powerful chemotactic agents, the leukotactic fractions obtained from zymosan-activated serum and the chemotactic factor produced by *E. coli*. Bacterial factor was obtained from overnight culture fluid of rapidly replicating *E. coli* cultures (WHO strain 16). The bacteria were removed by centrifugation and the factor was diluted 1/5 before use. Leukotactic fragments were obtained from serum by incubation with 10 mg zymosan per ml of serum at 37 °C for 1 h. When media from PTH-resorbed bones was added to the upper compartment or to both upper and lower compartments, there was no increase in movement of cells into the filters. Thus, increased movement of human monocytes into the membrane filters in response to resorbed bone media could not be ascribed to increased random cell migration.

The cells which were placed in the upper compartment of the Boyden apparatus at the beginning of the chemotaxis experiments were predominantly lymphocytes (85%). There were a smaller number of monocytes (15%) and polymorphonuclear leukocytes (<1%) (Fig. 1a). On the underside of the filter, only monocytes were observed (Fig. 1b). Thus, these experiments show that the chemotactic effect was directed towards monocytes and not lymphocytes or polymorphonuclear leukocytes. The absence of any effect on polymorphonuclear leukocytes

Table 2 Effect of different mediators of bone resorption on monocyte chemotaxis in Boyden chambers, using nitrocellulose filters with a pore size of 8 μm

Chemotactic sample	Bone resorption* (% ^{45}Ca release)	Chemotactic activity†
PTH (400 ng ml $^{-1}$) bone media	45 ± 8‡	48 ± 2‡
PGE_2 (10^{-7} M) bone media	32 ± 2‡	38 ± 2‡
$1\alpha, 25(\text{OH})_2 \text{D}$ (10^{-8} M) bone media	62 ± 4‡	55 ± 3‡
Control bone media	22 ± 1	32 ± 2
Dead bone media	14 ± 0.4	29 ± 2
Bacterial factor		52 ± 3‡

* Values are means $\pm$ s.e.m. for 6 pairs of bones.

† Chemotactic activity is expressed as the mean number of monocytes ($\pm$ s.e.m.) migrating into the filter per high power field (250 $\times$).

‡ Significantly greater than control bone sample ($P < 0.05$).

was confirmed by adding polymorphonuclear leucocytes alone to the upper compartment of the apparatus with resorbed bone media in the lower compartment. Although this PTH-treated bone media was actively chemotactic for monocytes, there was no increased chemotactic effect on polymorphonuclear leucocytes.

In another experiment, bones were incubated with two other humoral stimulators of bone resorption, 1,25-dihydrocholecalciferol and prostaglandin E₂ (Table 2). Media taken from these resorbed bones were also chemotactic for monocytes. There was a correlation between the extent of bone resorption and the chemotactic activity (Table 2). Thus, monocytes are attracted by media taken from resorbed bones independent of the humoral mediator of bone resorption.

The chemotaxis of monocytes towards resorbed bone products was also demonstrated using the technique of chemotaxis under agarose¹¹. In this method the cells migrate under semi-solid media in a tissue culture dish towards the adjacent chemotactic factor. A 10- μ l aliquot of cell suspension (containing 10⁶ cells) was placed in the centre well and four 19-d foetal rat radii and ulnae were placed in each outer well. In some dishes, PTH was added to the agarose-containing medium to stimulate the bones to resorb. Control dishes contained killed bones or unstimulated live bones. At the end of an 18-h incubation period in 5% CO₂ and air at 37°C, the cells were fixed with absolute methanol followed by formalin, and stained with Wright's stain. Migration was quantified by

Fig. 1 *a*, Wright's stain of human leukocytes applied to upper compartment of Boyden chamber apparatus (250 $\times$). These cells were predominantly lymphocytes with a small number of monocytes and polymorphonuclear leukocytes. *b*, Wright's stain of cells which migrated through the membrane filter in response to resorbed bone products (250 $\times$). All of the cells observed were monocytes in spite of the mixed cell population added to the opposite (upper) compartment. The small circles are the pores in the polycarbonate filter.

Fig. 2 Pattern of differential migration of human mononuclear cells in response to resorbing bones using the method of chemotaxis under agarose¹¹. Resorbing bones were in the outer well and the leukocytes (10⁶ cells in 10 μ l) were placed in the inner well. PTH (400 ng/ml) was added to the agarose medium. Distance A is the distance the cells migrated from the edge of the inner well towards the resorbing bones. Distance B represents spontaneous migration. The cells which migrated toward the bones in the outer well were monocytes.

projecting the pattern on to a white background and measuring the linear distance the cells had migrated toward the bones. In those dishes in which PTH was present, the bones were visibly resorbed and there was linear movement of the cells towards the wells containing the bones (Fig. 2). There was no elliptical ring of cells in dishes without PTH or in dishes which contained dead bones. The front advancing towards the resorbed bones comprised over 95% monocytes by light microscopic appearance.

The chemical nature of the factor or factors released by bone which is chemotactic for monocytes awaits further study. Small molecular weight factors such as calcium cannot account for these chemotactic effects since medium taken from PTH-treated bones did not lose chemotactic activity after dialysis. It is more likely that a fragment or product of bone matrix digestion is responsible. Postlewaite and Kang¹² have found that collagen-peptide fragments of chick and human skin collagen obtained by digestion with cyanogen bromide and pepsin or collagenase were chemotactic for monocytes but not for polymorphonuclear leukocytes. However, skin collagen differs chemically from bone collagen and whether similar chemotactic peptides are released during the bone resorption process is unknown.

The attraction of monocytes to bone resorbing margins may be of both physiological and pathological importance. Mononuclear cells are often found adjacent to bone-resorbing surfaces. Their role *in vivo* is unknown but it is possible that they participate in the bone-resorbing process because they are capable of resorbing bone *in vitro*^{1,2}. In addition, there is strong circumstantial evidence that osteoclasts, the major bone-resorbing cells, are derived from circulating mononuclear cells³⁻⁷. Thus, whether monocytes are precursors of osteoclasts or are bone-resorbing cells themselves, or both, the control of their movement to active bone margins may be a process of fundamental importance in bone resorption.

Loss of immunoreactivity in long-term bone marrow culture

WE have developed a long-term bone marrow culture system in which proliferation and differentiation of apparently functionally normal haemopoietic stem cells (CFU-S) can be sustained *in vitro* for several months¹⁻⁸. We now find that genetic resistance^{9,10} or host-versus-graft (H-v-G) reaction, the (possibly) related natural killer (NK) cell activity¹¹ and the ability of cultured cells to reconstitute irradiated allogeneic (non-compatible) recipients (with the subsequent development of G-v-H disease¹²) are all absent from such cultured cells.

The maintenance of stem cells *in vitro* seems to depend on prior establishment of populations of marrow derived adherent cells (including endothelial cells, large, fat-containing cells and macrophages) which we speculate provide a suitable microenvironment necessary for sustained haemopoiesis^{2,3}. When such adherent layers are seeded with freshly isolated syngeneic or allogeneic marrow⁴, the stem cells migrate into the adherent layer and undergo extensive self-renewal, liberating cells into the growth medium⁵. Such cells can be collected and assayed at weekly intervals, and allow monitoring of events occurring in the cultures. Concomitantly with self-renewal, stem cells undergo differentiation to a variety of progenitor cells, including CFU-C (granulocyte/macrophage progenitors) and CFU-M (megakaryocyte precursors)^{1,6,7}. While subsequent development of BFU-E into mature erythroid cells does not occur in the culture system, it maintains maturation of CFU-C and CFU-M into mature granulocytes/macrophages and megakaryocytes respectively^{1,7}. No B- or T-lymphocytes are detected after the first week, although recent work indicates that a precursor cell, 'specific' for lymphopoiesis, is present even after several weeks⁸. This system has now been used to study the mechanisms underlying the phenomenon of bone marrow transplantation resistance.

When limited numbers of bone marrow cells from certain parental mice, for example C57BL/6, are injected into irradiated BDF₁ hybrids (C57BL/6 × DBA/2) a rejection mechanism ensures the killing of these cells within the first 1-2 days^{9,10}. This 'genetic resistance' is determined not by the H-2 antigens, but by non-codominantly inherited haemopoietic histocompatible

Table 1 Maintenance of stem cells (CFU-S) in allogeneic bone marrow chimaeras *in vitro*

Adherent layer	Cells inoculated		CFU-S maintenance	
	BDF ₁	C57BL/6	3DF ₁	C57BL/6
BDF ₁	1:1		>5 weeks	>5 weeks
	1:9		>5 weeks	>5 weeks
	9:1		>5 weeks	>5 weeks
	19:1		>5 weeks	>5 weeks
	1:19		>5 weeks	>5 weeks

Adherent layers established from BDF₁ femoral marrow¹ were inoculated after 3 weeks with 10 ml of growth medium containing different ratios of BDF₁:C57BL/6 bone marrow cells, to a final concentration of 10⁶ nucleated cells per ml. The cultures were then fed at weekly intervals¹ and the non-adherent cells assayed for CFU-S²¹ in BDF₁ and C57BL/6 recipients respectively. It had previously been established that at the cell numbers injected cultured C57BL/6 CFU-S would not form spleen colonies in BDF₁ mice and vice versa.

antigens (present on the surface of primitive haemopoietic cells) and *I*r genes, which determine the responsiveness. The cell-type involved in the rejection process seems to be bone-marrow derived, and shares properties in common with macrophages¹⁰. Previous work showed that the BDF₁-derived bone marrow adherent layers would support the growth of semi-allogeneic C57BL/6 parental stem cells⁴ and it was suggested that either the effector cell involved in genetic resistance was not present within the adherent layer population, or that the effector cell system had been 'swamped' by inoculation of excessive numbers of target cells. In more recent work, we have shown that a BDF₁ adherent layer will support the growth of very low numbers of semi-allogeneic stem cells. Using published procedures^{1,4} BDF₁ marrow cells were allowed to form an adherent layer for three weeks at which time all the growth medium was removed, and the adherent layer gently washed with growth medium. The cultures were then reconstituted with 10 ml of growth medium containing various ratios of BDF₁:C57BL/6 bone marrow cells, at a final concentration of 10⁶ cells per ml. The results (Table 1) show that irrespective of the cell combination used, there is always extensive proliferation and differentiation of both stem cell populations (in some experiments it has been possible to show proliferation of three or even four bone marrow stem cell chimaeras *in vitro*) and no evidence of rejection of the relatively low numbers of semi-allogeneic stem cells was observed.

When equal numbers of freshly isolated BDF₁ and C57BL/6 bone marrow cells were mixed, and allowed to establish an adherent layer before inoculation with DBA/2 bone marrow cells, stem cell proliferation was also observed—direct mixing of semi-allogeneic or allogeneic marrow cells did not inhibit the capacity of the adherent layer formed to support haemopoiesis, indicating also that the important milieu producing cells are not destroyed in such circumstances.

The clear association between effector cells involved in genetic resistance and natural killer (NK) cells¹¹ led us next to examine NK activity in these cultures (Table 2). The activity in freshly isolated marrow cells was appreciably lower than that seen with spleen cells, but culture of either spleen or bone marrow cells resulted in a rapid decline in activity—falling to levels not significantly above the background within 24 h following spleen cell culture. The loss of NK cell activity in the cultures, and the lack of response against allogeneic marrow grafts, supports the contention that similar effector cells are involved in both phenomena. Interestingly, resistance to certain leukaemia viruses and tumour cells has also been shown to be mediated by cells having characteristics in common with NK cells and host-versus-graft effector cells, suggesting that there may be a common effector cell^{11,14,15}. Yet, in studies with leukaemia virus infection of long-term bone marrow cultures, we have demonstrated the continued maintenance of resistance

Table 2 NK cell activity in normal or cultured spleen and bone marrow cells (BDF₁ mice)

Effector: target cell ratio	Normal spleen Expt		Cultured spleen non-adherent cells 24 h Expt		Cultured spleen non-adherent + adherent cells 24 h Expt		Cultured spleen non-adherent + adherent cells 7 d	Normal bone marrow	Cultured bone marrow 7 d
	1	2	1	2	1	2			
100:1	27.0	30.7	2.8	1.9	1.1	2.3	6.8	12.0	3.3
50:1	13.7	16.7	1.9	1.0	1.2	1.1	3.2	6.5	0.8
25:1	9.4	7.7	1.7	1.1	1.1	1.5	6.0	3.4	0.0

Spleen cultures were established by inoculating 10⁸ spleen cells into culture flasks containing 10 ml of growth medium¹. Various times later the non-adherent cells were collected and assayed separately, or as a mixture, with the adherent cells for NK activity. Bone marrow cultures were established in the conventional way¹ and assayed 7 d after inoculation of the second bone marrow population. NK cell activity was measured by the cytotoxicity of spleen or bone marrow cells against ⁵¹Cr labelled K562 human CML in blast crisis target cells. 10⁴ K562 and varying numbers of effector (marrow or spleen) cells were incubated overnight and the ⁵¹Cr release from the cells measured according to published procedures²². Similar results were obtained when YAC-1 target cells were used.

in vitro^{16,17}. The cell type involved in this type of resistance, therefore, seems to be distinct from NK cell or H-v-G activity.

The possibility that cultured stem cells could be used to reconstitute the haemopoietic system of irradiated allogeneic mice, without the development of H-v-G disease, was indicated by our finding that T lymphopoiesis was not maintained in the cultures (since T lymphocytes are the effector cells involved in the H-v-G response⁸). Figure 1 demonstrates that 90% of BDF₁ mice, injected with normal C57BL/6 bone marrow cells, died within 70 d post reconstitution. On necropsy the mice had grossly enlarged spleens indicative of G-v-H disease^{12,19}. At this time only 20% of mice reconstituted with cultured C57BL/6 stem cells had died—with most of the deaths occurring in the first 4 weeks after reconstitution. At 120 d after reconstitution, some mice from this group were sacrificed, and the femoral marrow cells were assayed for CFU-S using irradiated BDF₁ and C57BL/6 mice as recipients. Spleen colonies developed only in the latter strain, showing that the cultured C57BL/6 marrow cells had indeed reconstituted the original BDF₁ recipients. Injection of cultured bone marrow cells, therefore, gives a situation analogous to that seen following reconstitution of irradiated mice with marrow cells which have been selectively depleted of T lymphocytes by immunological techniques^{18,20}.

Fig. 1 Survival of irradiated BDF₁ mice reconstituted with normal (●) or cultured (○) C57BL/6 bone marrow cells. C57BL/6 bone marrow adherent layers, established for three weeks, were 're-charged' with 10⁷ C57BL/6 bone marrow cells. The cultures were fed weekly by demi-depopulation. Two and three weeks later, the cells were collected and 5 × 10⁶–10⁷ cells containing approximately 750–1,500 haemopoietic stem cells or CFU-S²¹ were injected into irradiated (800 rad X rays) BDF₁ mice. Control mice received 5 × 10⁶–10⁷ freshly isolated (not cultured) C57BL/6 bone marrow—containing approximately equal numbers of CFU-S. Each group comprised 40 animals.

The significance of the present observations lies in the possibilities of establishing human cultures using allogeneic bone marrows and the potential of exploiting such cultures for the production of stem cells for marrow transplantation purposes (without the disadvantages of developing G-v-H disease). Furthermore, the absence of mature B, T and NK cells, in the murine system is allowing work on the genesis of these cells from the pluripotent haemopoietic stem cell.

Hepatic glucocorticoid receptors and the H-2 locus

VARIOUS inbred strains of mice exhibit different degrees of susceptibility to both spontaneous and glucocorticoid-induced cleft palate^{1,2}, and specific genetic and biochemical factors that may be responsible for these differences have been identified. At the genetic level, variations at the H-2 locus have been associated with susceptibility to glucocorticoid-induced cleft palate^{3,4}, while at the biochemical level, evidence suggests that numbers and characteristics of glucocorticoid receptors in murine embryonic facial mesenchyme cells differ in the various

strains. Specifically, Salomon and Pratt showed that facial mesenchyme cells cultured from fetuses of the A/J strain (which is highly susceptible to glucocorticoid-induced cleft palate) contain twice as many glucocorticoid receptors as do such cells from C57BL/6J, a low susceptibility strain⁵. They also reported that the glucocorticoid receptor of the A/J strain has a lower affinity for dexamethasone ($K_D = 1.7 \times 10^{-8}$ M) than does that of the C57BL/6J strain ($K_D = 7.9 \times 10^{-9}$ M) (ref. 5). In an attempt to relate steroid receptor activity to *H-2* haplotype, Goldman *et al.* used ³H-cortisol and isoelectric focusing to study glucocorticoid receptors in facial mesenchyme cells of these and several other strains⁶. They concluded that "a product of a gene in or near the *H-2* locus seems to be the glucocorticoid receptor, the level of which must be increased for a congenital malformation to occur". Such conclusions must be questioned, however, because the experimental procedure required micro-electrofocusing of isolated protein-cortisol complex for 40 h. Receptor binding is reversible, and in the absence of free steroid, the half life of the receptor-cortisol complex is only about 1 h at 0 °C (ref. 7). It is unlikely that a peak of radioactivity detected by isoelectric focusing after 40 h represents binding to a specific receptor. Thus an association between *H-2* haplotype and glucocorticoid receptor activity has not been established definitively. However, the possibility that *H-2* might determine hormone receptor levels or characteristics is exciting. We have explored the relationship between *H-2* and glucocorticoid receptors by examining the level of specific glucocorticoid-binding activity in liver cytosols prepared from different mouse strains.

Liver is suitable for such studies because liver cytosol preparations tend to have a relatively stable glucocorticoid-binding activity^{8,9}, while unbound glucocorticoid receptor molecules undergo rapid, temperature-dependent inactivation in most other cell-free systems. The liver is also well characterised as a target of glucocorticoid action, and *H-2* is expressed in this organ¹⁰. Thus an effect of *H-2* haplotype on the amount or affinity of specific glucocorticoid binding should be observed in this tissue. We examined specific glucocorticoid binding in the two strains studied by Salomon and Pratt, A/J (high susceptibility) and C57BL/6J (low susceptibility), as well as in the two *H-2* congenic lines A.BY and B10.A.

Because glucocorticoid-receptor inactivation is greatly accelerated at elevated temperatures⁷, we took care to prepare and maintain the liver cytosol at 0 °C. Adult males were killed by decapitation. Livers were removed and chopped on glassine paper over dry ice, weighed and transferred to a chilled homogeniser. Four volumes of ice-cold buffer (10 mM Tris, pH 7.35, 0.1 mM EDTA) were added and the tissue was homogenised on ice with nine strokes of a motor-driven Teflon pestle. The homogenate was centrifuged at 35,000g for 30 min, the supernatant was removed and assayed for glucocorticoid-binding activity.

Figure 1 shows binding of ³H-TA to the macromolecular component of liver cytosol as a function of free steroid concentration for the A/J and C57 strains. Nonspecific binding (binding of ³H-triamcinolone acetonide (TA) in the presence of an excess of cold dexamethasone) is the same in both strains, whereas total binding is significantly higher in A/J. Specific binding (total less nonspecific, upper inset, Fig. 1) is about twice as high in A/J as it is in C57. Scatchard plots of the data (Fig. 1, lower inset) suggest a single class of high-affinity binding sites. The initial slopes, representing specific binding, are approximately equal, giving an apparent K_D of 1.8×10^{-8} M for both the A/J and C57 strains. Experimentally determined values for specific binding and apparent dissociation constants can be affected significantly by inactivation of the unbound receptor. Rates of receptor inactivation must be similar in cytosol preparations from the two strains before values for dissociation constants and specific binding can be usefully compared¹¹. Figure 2 shows the decline of specific binding activity observed when liver cytosol is incubated in the absence of free steroid for increasing periods. Rates of inactivation of unbound receptors

Fig. 1 Binding of ³H-TA presented as a function of free steroid concentration. Samples of 0.2 ml of liver cytosol were incubated in a total volume of 0.5 ml for 22 h at 0 °C with various concentrations of ³H-TA ($21.6 \text{ Ci mmol}^{-1}$) in the presence of vehicle or a high concentration (5×10^{-5} M) of competing, nonradioactive dexamethasone. The bound steroid was separated from the free compound by passage through columns (1 cm $\times$ 22 cm) of Sephadex G-25 with an elution buffer of 0.01 M Tris (pH 7.35), 0.04 M KCl. The columns were run at 4 °C. Fractions (1 ml) were collected and the macromolecular peak was identified by the presence of blue colour resulting from the addition of two drops of a solution of blue dextran to each sample immediately prior to application to the column. Each point represents the binding expressed as pmol bound per mg of protein. Binding in the presence of vehicle: $\blacksquare$, A/J; $\bullet$, C57BL/6J, binding in the presence of nonradioactive dexamethasone (nonspecific binding); $\square$, A/J; $\circ$, C57BL/6J. The upper inset shows specific binding (total minus nonspecific) for each strain. Bound TA (pmol per mg of protein) is plotted against unbound TA ($\text{M} \times 10^5$). The lower inset presents Scatchard plots of the binding in the presence of vehicle. The ratio of bound to unbound TA is plotted against bound TA ($\text{M} \times 10^{10}$).

are the same in both strains. These rates and the observed levels of glucocorticoid binding were not affected by dithiothreitol.

To determine whether or not differences in glucocorticoid-receptor activity observed in the two strains are mediated by the *H-2* locus, activities of glucocorticoid receptors in the two congenic lines, A.BY and B10.A, were determined. A.BY has the *H-2^b*-region of the C57 strain placed on the A genetic background, while B10.A has the C57 background, but the A/J *H-2^a*-region. The results are shown in Table 1. The mean specific binding capacities in the four strains are significantly different ($P < 0.002$), however the difference is due to genetic background ($P < 0.001$) and not *H-2* ($P = 0.99$). There is some possibility of an *H-2* $\times$ background interaction effect ($P = 0.10$), which in this case would mean that the effect of genetic background on levels of glucocorticoid receptors is more pronounced in the presence of the *H-2^b*-haplotype than in the presence of the *H-2^a*-haplotype.

Thus we have shown that (1) rates of glucocorticoid-receptor inactivation are the same in both A/J and C57BL/6J mice; (2) affinities of the receptors for TA are the same in both strains; (3) A/J has approximately twice as many glucocorticoid receptors as C57BL/6J, and (4) this difference is not determined by variations at the *H-2* locus.

It is interesting to compare our results with what is known about spontaneous and glucocorticoid-induced incidence of cleft palate in these strains. The incidence of cortisone-induced cleft palate in A/J is 100%, in B10.A, 81% and C57, 21% (ref. 4), which corresponds in rank order to the observed levels of

Table 1 Relationship of specific glucocorticoid-binding capacity to *H-2* and genetic background

Background	Haplotype	
	<i>H-2</i> ^a	<i>H-2</i> ^b
A	A/J	A.BY
	1.29 ±0.11 (10)	1.49 ±0.16 (9)
C57Bl	B10.A	C57Bl
	0.99 ±0.10 (9)	0.83 ±0.09 (10)

Incubations (0.5 ml) containing liver cytosol and 6×10^{-8} M ³H-TA in the presence of vehicle or nonradioactive competing dexamethasone were maintained for 3 h at 0 °C. Specifically bound steroid was determined as outlined in the legend to Fig. 1. The numbers represent mean specific binding (pmol of ³H-TA bound per mg of cytosol protein) ± standard error for each of the four strains. Specific binding was determined in duplicate for each animal. The number of animals used to determine each mean is given in parentheses.

glucocorticoid receptors in these strains. The steroid-induced frequency of cleft palate in A.BY was not studied, but in our laboratory it has the highest spontaneous incidence of cleft palate of all four strains (19, 3, 0 and 0% for A.BY, A/J, B10.A and C57, respectively). Because A.BY also has the highest level of steroid receptors, glucocorticoid receptor levels may be an important determinant of susceptibility to spontaneous cleft palate in mice.

Although susceptibility to glucocorticoid-induced cleft palate has been shown to be partially controlled by *H-2* haplotype, these data demonstrate that the level of hepatic glucocorticoid receptors is determined by other genetic differences between the strains. Whether the factors controlling the levels of binding activity in liver reflect those that operate in the mesenchymal cells of the fetal palate is of course open to question. We observe the same difference in glucocorticoid binding capacity in liver as was seen by Salomon and Pratt in cultured fetal facial mesenchyme cells. This strongly suggests that the observed genetic control of receptor levels is not tissue specific. Our data, unlike theirs, do not suggest different affinity constants for the receptors in the two strains. Differences in binding capacity between the strains could arise from differences in the rates of receptor synthesis or degradation, or as has been suggested¹²⁻¹⁴, differences in rates of receptor activation and/or inactivation. Given the equivalent rates of inactivation presented in Fig. 2, the latter does not seem to be likely in this case.

Fig. 2 Unbound-receptor inactivation at 0 °C. Liver cytosol was incubated at 0 °C in the absence of labelled steroid for various times, after which saturating levels (6×10^{-8} M) of ³H-TA were added in both the presence and absence of an excess of cold dexamethasone. Specifically bound steroid was determined as described in the legend to Fig. 1. ■, A/J; ○, C57.

Although *H-2* is not the locus of prime importance in determining levels of hepatic glucocorticoid receptors in these strains, it may still be possible, using recombinant inbred lines, to identify specific loci which do regulate levels of glucocorticoid receptors. It may be particularly informative if lines with high levels of receptors and low susceptibility to glucocorticoid-induced cleft palate could be found.

We thank Ken Harper for technical assistance. Financial support was provided by the NSF and by grants CA16041 and GM15419 from the NIH.

Effect of L-triiodothyronine on (–)³H-dihydroalprenolol binding and cyclic AMP response to (–)adrenaline in cultured heart cells

MANY physiological responses of the cardiovascular system to thyroid hormone seem to reflect altered sympathetic activity. The effects of thyroid hormones on the heart are very similar to those induced by catecholamines and the possible interrelationship of these substances on myocardial function has been explained by an interaction at various levels. These include effects on altering catecholamine release from the sympathetic nervous system^{1,2}, and modifying plasma catecholamine concentrations^{3,4}, as well as tissue catecholamine content⁵ and responses⁶⁻⁸. Although several investigators have attempted to define an action of thyroid hormone and its possible role in potentiating the catecholamine response, the mechanism responsible for this modification has not been clarified. We have reported previously that physiological concentrations of L-triiodothyronine (T₃) stimulate the rate of glucose metabolism in cultured heart cells prepared from newborn rats⁹. We now demonstrate here that cultured heart cells retain the characteristic of response to β-adrenergic stimulation and that this response seems to be influenced by T₃.

The heart cells were prepared as described previously^{9,10}. The trypsinised cells were inoculated into 25-cm² plastic T-flasks (Falcon) at densities of approximately 200,000 cells cm⁻² and then grown in Ham's medium (Gibco) supplemented with 10% fetal calf serum (FCS) at 37 °C (95% air, 5% CO₂).

Catecholamine action seems to involve activation of adenylyl cyclase, which then leads to an increase in the intracellular concentration of cyclic AMP¹¹. Therefore we examined the cyclic AMP response to (–)adrenaline and the inhibitory effect

Fig. 1 Dose-response relationship of *a*, (-)-adrenaline stimulation of cyclic AMP production and *b*, (-)-alprenolol inhibition of the (-)-adrenaline-induced cyclic AMP response in the cultured heart cell. *a*, After 5 d growth of the culture, the culture flasks were partially submerged in a water bath at 37 °C for 2 min, to enable there to be precise temperature control during the experiment. The upper surface of the flasks was then opened with a haemostat. Various concentrations of (-)-adrenaline bitartrate (Sigma) dissolved in Ham's F-10 medium was added to the culture media. After a 2-min incubation, the media were aspirated and 1 ml of 10% ice-chilled trichloroacetic acid (TCA) was added. The cellular material was then removed using a rubber policeman at 4 °C and the samples were centrifuged at 2,000g for 15 min. The cell TCA precipitates were analysed for DNA by the method of Burton²⁰, and the supernatant was used for cyclic AMP assay by a modification of competitive binding method of Gilman²¹. The concentration of (-)-adrenaline which induced a half-maximal cyclic AMP response was 0.2 µM; above a concentration of 1 µM, (-)-adrenaline induced a maximal cyclic AMP response. *b*, Blocking effect of (-)-alprenolol on (-)-adrenaline-induced cyclic AMP production in a dose-related fashion. Various concentrations of (-)-alprenolol were added to the culture for 30 min before the addition of (-)-adrenaline (1 µM). The concentration of (-)-alprenolol which gave half-maximal inhibition was approximately 0.27 µM.

of the catecholamine antagonist, (-)-alprenolol, on the heart cell cultures. (-)-Adrenaline bitartrate at 1 µM, induced a sixfold increase in intracellular cyclic AMP within 2 min of incubation, which subsequently declined to a plateau higher than the basal level for up to 30 min. The intracellular cyclic AMP in cultured heart cells responds to (-)-adrenaline in a dose-related fashion; at concentrations greater than 1 µM, (-)-adrenaline induces a maximal response (Fig. 1*a*). This response of cyclic AMP can be antagonised effectively by (-)-alprenolol, which is a potent β -adrenergic antagonist, also in a dose-dependent fashion (Fig. 1*b*). The effect of preincubation of the cells with various concentrations of (-)-alprenolol for 30 min before induction of cyclic AMP by (-)-adrenaline was studied. (-)-Alprenolol at concentrations greater than 1 µM completely inhibited the adrenaline-induced cyclic AMP response, indicating that the cultured heart cells possess a biologically responsive β -adrenergic receptor.

It is generally felt that the physiological action of catecholamine agonists which result in an increase of intracellular cyclic AMP are mediated by a β -adrenergic receptor¹². Binding sites with the specificity of β -adrenergic receptor determined by (-)-³H-dihydroalprenolol binding have been identified in avian

and amphibian erythrocytes¹³, human lymphocytes¹⁴, and canine myocardium¹⁵. We have also demonstrated that specific binding of (-)-³H-dihydroalprenolol to cultured heart cells was very rapid at 37 °C, attaining equilibrium within 5 min. This binding can also be displaced equally rapidly by catecholamine agonists and antagonists.

We have examined the influence of T_3 on β -adrenergic responses, by measuring (-)-³H-dihydroalprenolol binding and the cyclic AMP response to (-)-adrenaline. The heart cells were grown first in regular growth medium and then this was replaced with Ham's F-10 medium supplemented with 10% hypothyroid calf serum. The cells remained in the second medium for 24 h, in order to deplete thyroid hormone. The culture medium was then

Fig. 2 Effect of L-triiodothyronine on (-)-³H-dihydroalprenolol binding (upper), cyclic AMP response (-)-adrenaline (lower). The heart cell cultures were prepared as described in the text. T_3 at 5 nM was added to one group of flasks. At the times indicated, (-)-³H-dihydroalprenolol binding and the cyclic AMP response to (-)-adrenaline (1 µM) were measured. For study of (-)-³H-dihydroalprenolol binding, the cells were scraped off the flasks with a rubber policeman and then washed twice with 10 ml of 0.145 M NaCl by centrifugation. The cells were suspended in 50 mM Tris-HCl buffer (pH 7.4 at 25 °C) containing 10 mM MgCl₂. Binding studies were carried out by incubating the cells (equivalent 12–18 µg of cell protein per tube) at 37 °C with 80 nM of (-)-³H-dihydroalprenolol (NEN, 32.5 Ci mmol⁻¹) in a total volume of 150 µl of incubation buffer. This concentration of (-)-³H-dihydroalprenolol gives maximal binding in the culture heart cells. The incubation was terminated by addition of 2 ml of ice-chilled buffer solution, followed by rapid vacuum filtration through Whatman GF/C glass fibre filters with a Millipore sampling manifold. The filters were then washed with 12 ml of ice-chilled buffer and were dried overnight at room temperature. The samples were counted with a Beckman liquid scintillation spectrometer with Aquasol solution (NEN). Nonspecific binding was determined by measuring the amount of radioactivity retained in the presence of a 10,000-fold excess of non-radiolabelled (-)-alprenolol (Sigma). The specific binding illustrated represented the total minus the nonspecific binding. An aliquot of cell suspension from each experiment was analysed for DNA content by the method of Burton²⁰ and cellular protein by the method of Lowry *et al.*²². The cellular protein-DNA ratio was not affected by thyroid hormone during the period of experiments. After incubation for 24 h, T_3 induced a significant increase in the (-)-³H-dihydroalprenolol binding and in the cyclic AMP response to (-)-adrenaline. Δ , With T_3 (5×10^{-9} M); $\bullet$, without T_3 .

Fig. 3 Effect of T₃ on *a*, (-)-³H-dihydroalprenolol binding and *b*, (-)-adrenaline-induced cyclic AMP response. The cultured heart cells were incubated with medium containing various concentrations of T₃ for 24 h and the (-)-³H-dihydroalprenolol binding (*a*) and cyclic AMP response to 1 µM of (-)-adrenaline (*b*), were studied simultaneously. T₃ affected both responses in a dose-related fashion. T₃ alone seemed to have no effect on the intracellular cyclic AMP level. ●, With 1 × 10⁻⁶ M (-)-adrenaline; ○, without (-)-adrenaline.

altered a third time, by adding 5 nM of T₃ to one group of flasks. (This concentration of T₃ has been shown to induce the maximal rate of glucose metabolism in cultured heart cells⁹ and growth hormone production in cultured GH₁ cell system¹⁶, a well established cell-culture system which is responsive to physiological concentration of thyroid hormone.) After 24 h of incubation, T₃ induced a significant increase of (-)-³H-dihydroalprenolol binding on culture heart cells (Fig. 2). The cyclic AMP response to (-)-adrenaline was similarly increased by T₃.

We next examined the influence of T₃ concentrations on (-)-³H-dihydroalprenolol binding and the cyclic AMP response to 1 µM (-)-adrenaline. As shown in Fig. 3*a*, (-)-³H-dihydroalprenolol binding was increased by thyroid hormone in a dose-dependent fashion. The cyclic AMP response to (-)-adrenaline was also enhanced by thyroid hormone in an identical fashion (Fig. 3*b*). The concentration of T₃ (0.3 nM) which resulted in a half-maximal stimulation of cyclic AMP by (-)-adrenaline and a half-maximal increase in (-)-³H-dihydroalprenolol binding is virtually identical. Cells incubated with 5 nM of T₃ showed almost a twofold increase in (-)-³H-dihydroalprenolol binding.

L-Triiodothyronine does not affect cell growth as reflected by total cellular DNA or protein content of the cultured cells⁹. The increase in (-)-³H-dihydroalprenolol binding therefore seems to be influenced selectively by T₃ and to be independent of total cell protein. The possibility cannot yet be excluded that T₃ may induce an alteration in membrane structure which cannot be measured in this study¹⁹. Martin and co-workers reported the existence of a β-adrenergic receptor in 13-d-old fetal rat hearts¹⁷. Here we have demonstrated that the β-adrenergic response of cardiac tissue can be maintained in dispersed cultured condition and can be influenced by thyroid hormone in a dose-related fashion. Thyroid hormone has recently been

reported to increase the β-adrenergic receptor in rat myocardium¹⁸. The exact mechanism by which thyroid hormone regulates the β-adrenergic response requires further investigation.

Possible plasticity in the rat superior colliculus

THE potential for plasticity of the developing mammalian visual system has been the subject of several investigations^{1,2}. I have now explored the plastic relationship between different sensory modalities. The rodent superior colliculus was chosen as the model as it receives overlapping visual, somatic and auditory inputs^{3,4}. Electrophysiological comparison of dark-reared and normal rats suggests that the rat's superior colliculus is susceptible to effects of sensory deprivation during its postnatal development.

It has been shown in the mouse³ and the hamster⁴ that many neurones in the intermediate and deep layers of the optic tectum receive nonvisual sensory inputs. They respond either to somatic stimuli from fur or whiskers on the contralateral half of the body or to complex sounds from the contralateral side. Some of these cells also receive visual inputs and thus have a bimodal response; more rarely, trimodal cells responding to all three sensory modalities are also encountered. Further, for cells in any one electrode penetration that is nearly normal to the collicular surface, there is general topographical correlation between all the visual, somatic and auditory receptive fields.

In my study using black-hooded rats, I have compared normally reared (12 h light/dark cycle) and dark-reared rats for the relative abundance of the different types of single units in the superior colliculus. I adopted a double-blind procedure, in which the rearing condition of each animal was not revealed to me until I had completed recordings on all the rats. Twenty-nine rats (15 normal and 14 dark-reared), all approximately 20 weeks old and weighing about 300 g, were used in random order. Light deprivation was achieved by rearing the animals in a dark room and the only light they could have received until the time of recording was a few minutes of a red photographic light (<0.1 lm m⁻²) during cleaning of cages.

Table 1 Distribution of sensory cell types in the deeper layers of the superior colliculus of normal and light-deprived rats

	Visual	Somatic	Auditory	Visual/ somatic	Bimodal neurons Visual/ auditory	Somatic/ auditory	Trimodal neurons (visual/ somatic/ auditory)	Total
Normal rats	104 (46.2%)	85 (37.8%)	9 (4%)	18 (8%)	3 (1.3%)	3 (1.3%)	3 (1.3%)	225 (100%)
Light-deprived rats	56 (24.5%)	140 (61.1%)	24 (10.5%)	2 (0.9%)	0	7 (3.1%)	0	229 (100%)

The basic operating and recording techniques were similar to those used by Tiao and Blakemore⁴ for the hamster. Glass-coated tungsten microelectrodes with a tip length of 15–20 µm were used and single units were identified by the usual criteria⁵. As the superficial layers of the tectum are densely packed with visual cells even in the dark-reared rats, I have attempted to include in my count cells from intermediate and deep layers only. The occurrence of changes⁴ in the response properties to visual stimuli during an electrode penetration and prior histology indicated the approximate limit to the superficial layers to be 350 µm below the collicular surface. However, all cells encountered below 200 µm were included in the count. The surface of the superior colliculus was identified during the nearly surface-normal penetration by a characteristic change in the background noise, which responded to visual stimuli in the correct part of the visual field with a brisk hiss. The penetration was always continued to a depth of 2,200–2,500 µm, which was at least 500 µm beyond the last cell responding to a sensory stimulus. Histological reconstruction of the electrode tracks in some of the animals confirmed the reliability of our electrophysiological criteria for identifying the superior colliculus. All recordings were restricted to the parts of the superior colliculus whose visual field representation was between 40° and 80° from the midline, with the blind axis monitored at 70°. This was necessary because, towards the caudal end of the colliculus, representing the temporal end of the visual field, there is greater nonvisual input even in the normal rat, and towards the rostral end of the colliculus, representing the nasal end of the visual field, there is greater visual input even in the dark-reared rat. When tested ophthalmologically before recording, none of the rats used showed any obvious difference from the controls.

Table 1 shows the pooled results from 42 penetrations in 15 normal rats and 40 penetrations in 14 dark-reared rats. It can be readily seen that the ratio of nonvisual cells to visual ones has increased markedly in the light-deprived animals. Further, there is an almost total absence of multimodal cells with visual inputs in these animals. The increase in the number of nonvisual cells can be either a relative one due to functional or anatomical dropping out of the visual terminals or may reflect an active take-over of collicular neurones by nonvisual sensory inputs. I have attempted to resolve this question by comparing the mean distribution of cell types per penetration between the two groups of rats. It can be seen from Table 2 that the mean number of cells in a single penetration having visual input has significantly (two-tailed test: $P < 0.001$) decreased in the dark-reared rats. Further, the mean number of cells with nonvisual sensory inputs

has significantly ($0.001 < P < 0.01$) increased, suggesting an active process. This absolute increase in the mean number of neurones responding to nonvisual stimuli also makes it less likely that the reduction in the number of visually driven cells is due to any shrinkage of these cells in the light-deprived rat. However, the contribution of any retinal effects of light deprivation⁶ to the reduction in the number of recordable visual cells is an open issue.

It may not be too speculative to suggest that, at birth, the sensory inputs to the superior colliculus from the different modalities are in a state of competition and in the absence of normal stimulation in one of these channels, the other modalities may come to influence a larger proportion of cells. It does not, however, follow that the discriminative ability of the somatic and auditory systems in the light-deprived rat are, compensatively, better than, or even as good as that in the normal rat. The postnatal visual input may have a directive role in the development of the normal properties of the nonvisual and multimodal neurones of the optic tectum. In its absence, the somatic and auditory systems may in fact be permanently impaired.

I thank Professor J. Cronly-Dillon and Drs J. Kulikowski, G. Perry and R. Abadi for comments, and Mr B. Morrissey and Mr N. Ritchie for technical help.

Horizontal cells influence membrane potential of bipolar cells in the retina of the turtle

BIPOLAR CELL responses to illumination of the surround have been thought to be mediated by horizontal cells^{1,2}. However, it has been shown recently that the responses of bipolar cells to stimulation with an annulus of light are not suppressed by pharmacological blockade of horizontal cell activity, so alternative mechanisms for the surround effect have been proposed³. The present experiments were performed to establish whether bipolar cells are in fact driven by horizontal cells, and whether the properties of such hypothetical interaction can account for the surround responses of bipolar cells.

Two intracellular microelectrodes were used simultaneously: one to pass current through the membrane of a horizontal cell, and the other to record the membrane potential of an adjacent

Fig. 1 Simultaneous recordings from L-type horizontal (hc) and bipolar cells. Bipolar cells were centre-hyperpolarising (c.h.b.c) in *a* and centre-depolarising in *d* and *e* (c.d.b.c). *a*, Photoreponses to brief illumination (25 ms, as indicated upper left) in the form of a spot, of 200 μm radius centred on the electrodes penetration site. The light source ($2 \times 10^5 \text{ erg cm}^{-2} \text{ s}^{-1}$, with wavelength between 400 and 800 μm) was attenuated by 3.6 log units. Note that the hc response is 25% of its maximal amplitude with bright light, while the c.h.b.c response has already reached the amplitude saturation level. *b*, Computer-averaged recordings from the same c.h.b.c as in *a*, in darkness. Each record represents the average of 8 sweeps. The lower line represents the duration of the horizontal cell artificial polarisation obtained with the current intensity indicated by the numbers at the right. The arrow in 1 points to the onset of the depolarising response of c.h.b.c as in *a*. *c*, Computer-averaged recordings from the same c.h.b.c as in *a*. Three superimposed averages of two photoresponses each, recorded without and with artificial horizontal cell hyperpolarisation, whose duration is indicated by the lower line. The arrows point to the onset of the c.h.b.c depolarising responses to current injections of the same intensities as in *b*. A spot of 500 μm radius was used for illumination. Duration of illumination is indicated approximately by the onset and the recovery phase of the c.h.b.s membrane potential. Light intensity as in *a*. *d*, Responses from a horizontal cell (hc) and a bipolar cell (c.d.b.c) to brief illumination (25 ms, as indicated at the upper left) in the form of a spot of 200 μm radius. Light attenuation was -3.6 log units. *e* 1, Superimposed recordings, from the same c.d.b.c as in *d*, of the hyperpolarising responses (arrow) to artificial hyperpolarisation of the horizontal cell; *e* 2, depolarising c.d.b.c responses to artificial depolarisation of horizontal cell. Duration of current injection is indicated by the lower line. Numbers to the right refer to the intensity of injected current. Time and voltage calibrations (100 ms, 5 mV) are indicated by the horizontal and vertical lines, respectively, shown as T symbols, at the right of each recording, from *a* to *e*.

bipolar cell. The methods for intracellular recording and light stimulation have been described elsewhere⁴.

Figure 1*a* shows the simultaneously recorded responses from an L-type horizontal cell and a centre-hyperpolarising bipolar

cell, identified according to criteria for turtle retina defined previously^{2,5}. The stimulating light, a spot of 200 μm radius, was centred midway between the electrodes, which were about 100 μm apart. When hyperpolarising current was passed through the horizontal cell membrane, a sustained depolarisation was recorded from the centre-hyperpolarising bipolar cells (Fig. 1*b*(1)). Increasing the current induced a larger response and reduced latency (Fig. 1*b*(2)). In this cell, the lowest detectable response was evoked by injecting $1.7 \times 10^{-9} \text{ A}$, which produced an estimated -1.7 to -3.4 mV change of horizontal cell membrane potential (assuming a horizontal cell input resistance of $1-2 \text{ M}\Omega$). Similar results were obtained during illumination (Fig. 1*c*), and the bipolar cell response to current injection disappeared when the electrode was withdrawn from the horizontal cell. On the other hand, centre-depolarising bipolar cells are hyperpolarised or depolarised, respectively, by passing hyperpolarising or depolarising currents through the horizontal cell membrane (Fig. 1*e*, 1 and 2).

Thus, in contrast to the conclusions of Piccolino and Gerschenfeld³, our data show that horizontal cell activity influences the membrane potential of bipolar cells in a way qualitatively consistent with the previously proposed role of horizontal cells in mediating surround effects. This result might be expected from published anatomical and physiological evidence—electron microscopy shows that horizontal cells are presynaptic to bipolar cells at presumed chemical synapses of conventional type^{1,6} while an indirect input to bipolar cells is provided by horizontal cell feedback onto cones⁷. Although the present results do not give information on the circuitry underlying the bipolar cell responses to horizontal cell stimulation, it seems reasonable to assume that both the direct and feedback pathways are involved. The participation of additional retinal elements in mediating the bipolar cell surround cannot be excluded.

Bilayers containing gangliosides develop channels when exposed to cholera toxin

CHOLERA toxin, a protein of molecular weight 84,000, comprising five or six B and one A subunits, produces massive diarrhoea in man and other mammals by altering the transport of salt and water across the intestinal epithelium¹⁻⁴. These effects are mediated by a sequence of events leading to an increase in the concentration of cyclic AMP in the epithelial cells. The sequence involves binding of the toxin through its B subunits to specific receptors which seem to be the monosialoganglioside galactosyl-*N*-acetyl-galactosaminyl-(*N*-acetylneuraminyl)-galactosyl-glucosyl-ceramide (GM_1), and subsequent activation of adenyl cyclase⁵⁻⁷. We report here experiments which show that cholera toxin reacts with lipid bilayers containing GM_1 to form channels which allow ions present in the aqueous solution to traverse the membrane.

Fig. 1 Time course of development of membrane conductance (G_m) of a bilayer containing 3% G_{M1} in GMO (●) and one containing 3% G_{M2} in GMO (★) after addition at time $t = 0$ of 10 ng ml^{-1} (●) or 15 ng ml^{-1} (★) cholera toxin to one chamber. GMO concentration was 12 mg ml^{-1} .

Bilayers were formed from a mixture of glycerolmonooleate (GMO) (Nu-Chek) and G_{M1} or G_{M2} (*N*-acetylgalactosaminyl-*N*-acetylneuraminyl)galactosyl-glucosyl-ceramide) (Supelco) in the molar ratios indicated. The lipid mixture was dissolved in chloroform-methanol (2:1, v:v) and spread on the water-air interfaces of the bathing solutions. After allowing the solvents to evaporate (approximately 30 min), $2 \mu\text{l}$ of decane were added to each of the interfaces, a procedure which increased the stability of the membranes. The bilayers were then formed by the technique first described by Montal and Mueller⁸ and described in detail by Hall and Latorre⁹. The area of black film could not be determined accurately by visual means (the diameter of the holes used in these studies was 0.36 mm). Therefore, an estimate was made from the measured capacitance of the films (690 – 740 pF) and the value of the specific capacitance for this type of membrane formed in the absence of decane at the interfaces, by pretreating the hole with a 2% solution of squalene in pentane ($0.84 \pm 0.02 \mu\text{F cm}^{-2}$). The aqueous solutions present in the 1.5-ml chambers contained initially 100 mM NaCl buffered to $\text{pH } 7.0$ with $5 \text{ mM Na-phosphate}$ buffer. The electrical characteristics were determined using a pair of Ag-AgCl electrodes to inject and measure current, and a pair of calomel electrodes to measure zero-current membrane potentials. When appropriate, a portion of a freshly diluted solution of cholera toxin (Schwarz-Mann) was added to one of the chambers.

Figure 1 shows the results of experiments in which cholera toxin was added to the aqueous solution bathing one side of GMO bilayers containing either G_{M1} or G_{M2} . An abrupt and substantial increase in membrane conductance was observed in the former but not in the latter case. GMO membranes did not respond to choleragen addition (not shown). Apparently, a

Fig. 2 Recorder trace showing the development of membrane conductance and current fluctuations for a GMO membrane containing 1% G_{M1} . GMO concentration, 12 mg ml^{-1} . Cholera toxin was added to a final concentration of 3 ng ml^{-1} . The jump in current shown was the only one, although at later times, current fluctuations of smaller values were also observed.

specific interaction between G_{M1} and cholera toxin is necessary to produce an increase in membrane conductance. This point was substantiated by experiments in which choleragen was mixed with excess G_{M1} and then added to the aqueous solution bathing one side of a bilayer containing G_{M1} . No increase in membrane conductance was observed. Subsequent addition of cholera toxin not previously mixed with G_{M1} to the opposite side of the membrane produced the usual conductance increase.

Examination of records of membrane current at constant membrane voltage and higher time resolution reveals the presence of current fluctuations (Fig. 2). These records are consistent with a picture in which ion-conducting channels with

Fig. 3 Dependence of the zero-current, zero-voltage steady-state conductance (G_m) on the concentration of cholera toxin at different molar ratios of G_{M1} in GMO (12 mg ml^{-1}). The points for 1% and 10% were obtained in three different membranes, each of which was exposed to at least three different concentrations of toxin. Those for 3% are all from different membranes, averaged values. The lines were drawn according to the equation in the text, with $K_m = 1.2 \times 10^{-10} \text{ M}$ and G_{max} values as indicated

a conductance of the order of 20 – 40 pS cm^{-2} randomly open and close during the experiment. The ionic selectivity of the channels was evaluated by measuring the zero-current membrane potential in the presence of known differences in the concentration of Na, K and Cl in the two aqueous bathing solutions. The results indicated that the channels are twice as permeable to the monovalent cations as to chloride, with practically no selectivity for Na over K.

Figure 3 shows the dependence of membrane conductance on cholera toxin concentration at three different mol fractions of G_{M1} in the membrane-forming solution. The bilayer conductance levelled off as the toxin concentration in the aqueous phases was increased, and so the data were fitted using a saturating type of relation between membrane conductance and toxin concentration:

$$G_m = \frac{G_{max}[\text{toxin}]}{K_{1/2} + [\text{toxin}]}$$

where G_m is the steady-state membrane conductance, G_{max} is the maximum membrane conductance at high toxin concentration, [toxin] is the concentration of cholera toxin in the aqueous phase and $K_{1/2}$ is the concentration of toxin which produced half the maximum conductance increase. The value of $K_{1/2}$ required to fit the data at the three concentrations of G_{M1} used is $1.2 \times 10^{-10} \text{ M}$, similar to the value found by Cuatrecasas for the interaction of choleragen with fat cell membranes⁵.

These data support a picture in which cholera toxin reacts with the sugar residues in the G_{M1} molecules in the membrane surface to produce a complex that forms ion-conducting channels. We are now investigating the size and kinetic properties of the single channels and the role of the different subunits of cholera toxin in

the process of channel formation. These experiments may help to clarify the mechanism by which cholera toxin, and perhaps other agonists, activate adenyl cyclase.

Human urinary kallikrein converts inactive to active renin and is a possible physiological activator of renin

WE have found that human urinary kallikrein converts inactive plasma renin *in vitro* to an enzyme with renin-like activity. This observation is interesting because renal kallikrein, the presumed precursor of urinary kallikrein¹, is thought to be situated in or on cells of the distal convoluted tubule, including the macula densa cells¹⁻³, which are adjacent to the storage site of renin, the juxtaglomerular cells⁴. Also, human urinary kallikrein is a trypsin-like enzyme of highly restricted specificity⁵, and although trypsin is capable of activating inactive renin⁶, we have found that kallikrein is at least 10 times more active. Therefore it seems possible that urinary kallikrein is the *in vivo* converting enzyme of prorenin and may activate the renin-angiotensin-aldosterone hormonal system, as it participates in sodium and potassium homeostasis⁴ and in the blood pressure maintenance of a majority of hypertensive patients⁷.

Inactive plasma renin can be converted *in vitro* to active renin by trypsin⁶, by exposure to cold (cryoactivation)^{8,9}, or by dialysis to pH 3.3 with subsequent restoration of neutral pH (ref. 10). We have shown that in plasma the major portion of the increase in renin following dialysis to pH 3.3 occurs at alkaline pH (refs 11, 12). Like cryoactivation, the alkaline phase of 'acid' activation seems to involve an unidentified endogenous neutral serine protease^{11,12}. As acidification of plasma destroys endogenous protease inhibitors^{13,14}, and as activation of inactive renin by endogenous proteases following acidification proceeds very slowly, we were able to use acidified plasma to test the potency of small amounts of highly purified urinary kallikrein¹⁵ on the conversion of inactive to active renin.

Pooled human plasma (50 ml, in presence of EDTA) with renin activity¹⁶ of 1.5 ng angiotensin I ml⁻¹ h⁻¹ was dialysed to pH 3.3 for 24 h at 4 °C. Two 1-ml samples were further dialysed from pH 3.3 to 7.4 at 4 °C for 24 h after which renin averaged 8.5 ng ml⁻¹ h⁻¹ (Fig. 1). Plasma renin activity was 4.5 ng ml⁻¹ h⁻¹ in the remainder of the pool which was adjusted to pH 7.4 and there was no further increase during 1 h incubation at 25 °C and pH 7.4. When urinary kallikrein or trypsin was added to this pool for 1 h at 25 °C, a 66% increase in renin activity was observed with urinary kallikrein 2 × 10⁻⁷ M but only a 39% increase with trypsin 2 × 10⁻⁶ M (Fig. 1). Maximum activation (that is, to 8.3 ng ml⁻¹ h⁻¹) was achieved by urinary kallikrein 4 × 10⁻⁷ M, whereas trypsin 8 × 10⁻⁶ M did not quite achieve maximum activation.

In another study urinary kallikrein at 0, 2.0 and 3.1 × 10⁻⁶ M was added to untreated plasma and incubated for 2 d at -4 °C. In the absence of urinary kallikrein there was a small increase in renin activity due to cryoactivation⁹. However, urinary kallikrein caused a concentration-dependent increase in the rate of cryoactivation (Fig. 2), thus demonstrating that activation of inactive renin by kallikrein does not depend on previous acidification.

Although inactive renin is present in the plasma of most anephric patients¹⁷, the data in Fig. 3 demonstrate that it is also of renal origin. Active and inactive plasma renin were measured in simultaneously collected renal vein and inferior vena caval (IVC) samples from a patient with renal artery stenosis. Active and inactive renin levels were the same in the IVC and right renal vein, but there were marked increments in both forms of renin in renal venous plasma from the left side, thus demonstrating renal secretion of both active and inactive renin.

Fig. 1 Activation of inactive renin in previously acidified plasma by urinary kallikrein, trypsin or endogenous serine proteases. Pooled human plasma (50 ml; EDTA) was dialysed to pH 3.3 for 24 h at 4 °C (0.05 M glycine-HCl, 0.1 M NaCl, 3 mM Na₂EDTA). This destroys endogenous protease inhibitors^{13,14} and activates about one-third of inactive plasma renin¹¹. Three methods of activation of the remaining inactive renin were tested. ■, Two 1-ml samples were further dialysed to pH 7.4 for 24 h at 4 °C (0.10 M sodium phosphate, 0.05 M NaCl, 3 mM Na₂EDTA) during which time endogenous proteases slowly activated inactive renin. The remainder (48 ml) was adjusted to pH 7.4 at 0 °C with 5 ml 4 M Tris, pH 7.4, and 0.5 ml 2 M NaOH. ●, Pure urinary kallikrein¹⁵ (specific activity 1094 µg equivalents bradykinin min⁻¹ mg⁻¹ at pH 8.5 and 37 °C); or △, trypsin (Boehringer Mannheim, specific activity 33 U mg⁻¹); or ○, distilled water, were added to 0.5 ml samples which were then incubated at 25 °C for 1 h. Activation was stopped by adjustment to pH 5.7 and addition of phenylmethylsulphonyl fluoride (PMSF) 1.5 mmol l⁻¹. Renin activity was then measured by incubation at pH 5.7 and 37 °C (ref. 16) after addition of partially purified human renin substrate¹¹. Results for urinary kallikrein were from three separate experiments.

Stop-flow² and histological studies³ have suggested that renal kallikrein is located in the cells lining the distal convoluted tubule extending from the juxtaglomerular apparatus (where renin is synthesised) to the collecting duct. Its activity has been associated with the plasma membrane and/or endoplasmic reticulum^{1,18} of cells from the renal cortex, although lysosomal fractions have also been implicated¹⁹. Thus, kallikrein may be present in the renin-secreting cells of the juxtaglomerular apparatus. Urinary kallikrein is reported to have a more restricted specificity than trypsin⁵ and is often catalytically less efficient^{20,21}. Its greater potency for activating inactive renin would therefore seem to favour specific interaction. This observation, together with its location in the kidney, suggests that kallikrein might be a prorenin converting enzyme. However, other mechanisms may be involved, as inhibitors of sulphhydryl-dependent enzymes have been reported to block conversion of

Fig. 2 Potentiating effect of urinary kallikrein on the rate of cryoactivation of inactive plasma renin: 100 or 200 μ l (2×10^{-6} and 3.1×10^{-6} M) purified urinary kallikrein or distilled water was added to 0.3 ml plasma (EDTA) which was then incubated at -4°C for 38 h (96 h are required for cryoactivation to reach a plateau). Renin was then assayed at pH 5.7 and 37°C in the presence of 1.5 mM PMSF. Renin activity, measured after cryoactivation in the presence of urinary kallikrein, is expressed as a percentage of that measured after 38 h cryoactivation alone.

large to small molecular weight hog renal renin with a resultant small change in activity²².

If kallikrein activates inactive renin *in vivo*, this would be the second link between the kallikrein and renin systems, as angiotensin-converting enzyme converts angiotensin I to angiotensin II and also hydrolyses bradykinin to inactive products²³.

So far, urinary kallikrein is the most potent activator of inactive renin yet described and may be strategically located to

Fig. 3 Unilateral renal secretion of active and inactive renin from a hypertensive patient with left renal artery stenosis. Blood specimens were collected from the IVC simultaneously with each renal vein blood collection. Inactive plasma renin was measured as the difference between endogenous renin activity and the renin activity following activation by trypsin (1 mg per ml plasma at -4°C for 1 h). There was no difference in active or inactive renin between the IVC and right renal vein, whereas a marked increment in both renins was observed from the left side, thus demonstrating the renal origin of both active and inactive renin.

participate in renin biosynthesis. Whether the enzyme is part of a biological control system for the release of renin and for the accomplishment of sodium, potassium and blood pressure homeostasis, remains to be established.

Specific and irreversible block of the myotropic action of angiotensin II

COMPETITIVE inhibitors of the octapeptide hormone angiotensin II (AT), Asp-Arg-Val-Tyr-Val-His-Pro-Phe, have been synthesized by several groups¹. These inhibitors, like the hormone, are quickly degraded, and no irreversible or even long-acting specific inhibitors have been available. Paiva *et al.*² have attempted to produce such inhibitors using affinity labelling analogues, but with poor results. We report here a specific and irreversible inhibition of the response of rabbit aorta strips to AT by a photolabile analogue of AT.

We previously described the synthesis³ and the biological activities⁴ of the AT analogue Sar-Arg-Val-Tyr-His-Pro-(4'-azido)Phe (=N₃-AT) in the absence of ultraviolet radiation. Also, (4'-azido)Phe has been successfully used as a photoaffinity label in studies on chymotrypsin⁵ and ribosomes⁶. In the present study, rabbit aorta strips were suspended in Krebs' solution according to the method of Rioux *et al.*⁷. Photolysis was carried out with four parabolic mercury vapour lamps (Westinghouse JC PAR-38) equipped with black light filters surrounding a tissue bath. The light was further filtered through pyrex glass and

Fig. 1 Contraction of rabbit aorta strips in various conditions. The interval between injections of angiotensin II (AT), 200 ng ml⁻¹, (Sar¹)-angiotensin II (Sar-AT), 200 ng ml⁻¹, or its photolabelling analogue (Sar¹(4'-azido)Phe⁸)-angiotensin II (N₃-AT), 200 ng ml⁻¹, was 90 min. Noradrenaline (NA), 50 ng ml⁻¹, was injected 30 min after AT, and (Leu⁸)-angiotensin II (I), 5,000 ng ml⁻¹, was added 15 min before the agonist. All tests have been carried out under total exclusion of UV radiation except when indicated. Dots indicate washing of the tissues. Contractions of the rabbit aorta strips suspended in tissue baths were recorded on a Grass polygraph with isometric force transducers. All other experimental details are as described by Rioux *et al.*⁷.

water so that almost only the 365-nm band of the mercury spectrum reached the tissue.

When tissues contracted by (Sar¹)-AT were irradiated, they relaxed immediately (Fig. 1a), analogous to the results reported by Furchgott *et al.*⁸. If the irradiation is discontinued the tissues regain their initial degree of contraction and are normally responsive to further applications of stimulants. In the dark, N₃-AT acts as a reversible agonist of the AT receptor (Fig. 1b); it has the same intrinsic activity as (Sar¹)-AT and a relative affinity of 31%. If the tissues contracted by N₃-AT (Fig. 1c) are irradiated, the strips relax as they do under the influence of light, but they do not recontract when the light is removed. They also lose their responsiveness to AT but not to noradrenaline (Fig. 1c), histamine, bradykinin, 5-hydroxytryptamine or potassium (not shown), agents acting on receptors different from those of AT. Further applications of AT during the following 2–6 h do not induce any significant rise in tension. If the same experiment is carried out in the presence of the competitive inhibitor (Leu⁸)-AT at saturating concentrations, the tissues recover their responsiveness to AT (Fig. 1d). The slight decrease in response observed is due to some desensitisation by the inhibitor and it also occurs in the same experiment without irradiation (Fig. 1e).

In some preparations (one out of five), in which the desensitisation of the tissues to AT achieved with photolysis of N₃-AT was less than 80%, the treatment was repeated and resulted in an almost complete inactivation.

Two possible reactions of the tissue were expected with a specific covalent block by an agonist. (1) The tissue stays contracted due to a continuous stimulation of the response by a stable hormone–receptor complex. This phenomenon has been reported with gastrin⁹. (2) Covalent attachment of the hormone to the receptor induces a permanent loss of hormone response, because stimulation occurs only when the receptor changes from 'bound' to 'unbound' or the reverse. If the hormone is irreversibly attached this dynamic process cannot occur again. We therefore conclude that, under photolysis, N₃-AT covalently and specifically blocks the receptor for AT. Studies using radioactive analogues of N₃-AT are now in progress in an attempt to isolate the AT receptor from arterial smooth muscle.

Evidence for an essential DNA component in the Scrapie agent

ONE of the enigmas of microbiology has been the nature of the aetiological agent causing scrapie disease in sheep and goats. The unusual resistance of infectivity to heat, formaldehyde, nucleases and UV irradiation has stimulated many hypotheses, including speculation that the scrapie agent may lack nucleic acid¹. This stability to physical and chemical inactivation has been due in part to the intimate association of the agent with the cell membrane^{2,3}, making it impossible to obtain soluble fractions of brain tissue containing high titres of infectivity. A

hamster model of scrapie disease has been developed^{4,5} that has shorter incubation periods and higher brain titres of infectivity than any other animal model. Studies on the subcellular distribution of scrapie agent in hamster brain have shown that 8–9% of the total infectivity can be found in membrane-free high-speed supernatant (HSS) fractions⁶. Infectivity in the HSS exists as small heterogeneous complexes which are resistant to detectable enzymatic degradation, but are more sensitive to inactivation by heat and UV irradiation than are cruder brain preparations⁷. We report here further partitioning of scrapie infectivity in the HSS using two methods of separation, hydroxyapatite chromatography and polyacrylamide gel electrophoresis, both of which result in isolation of a fraction of scrapie infectivity that is inactivated by deoxyribonuclease (DNase). We therefore conclude that the scrapie agent contains an essential DNA component.

Hydroxyapatite chromatography was performed as reported previously⁷. Briefly, brain homogenates in 12 mM sodium phosphate (pH 7.2) are centrifuged at 100,000g for 18 h in a Beckman 42.1 rotor and the supernatant fractions applied to a hydroxyapatite column at room temperature. Scrapie infectivity eluted in the 0.48 M sodium phosphate wash, and representing 1% of the total input infectivity to the column, was diluted 1:4 with buffer (100 mM Tris, 0.15 M NaCl, 12 mM sodium phosphate, pH 7.2), then treated with DNase I (Worthington), RNase A (Worthington) or proteinase K (Boehringer-Mannheim) at concentrations of 100 $\mu\text{g ml}^{-1}$, 50 $\mu\text{g ml}^{-1}$ or 62 $\mu\text{g ml}^{-1}$, respectively. Magnesium chloride (20 mM) was added to the tube containing DNase and also to the control tube which received no enzyme treatment. All preparations were then incubated in a water bath at 37 °C for 60 min. To ensure that the enzymes used were biochemically active in the conditions stated, they were individually tested on radioisotope-labelled substrates which were added directly to the scrapie sample to be treated. Scrapie infectivity was measured by intracerebral inoculation of weanling hamsters and endpoints calculated 16 weeks after injection using the method of Spearman and Kärber⁸. As can be seen in Table 1, only treatment with DNase resulted in substantial reduction of infectivity.

Because the above experiment indicated that infectivity was resistant to proteolytic digestion, a second sample of HSS was digested with 100 $\mu\text{g ml}^{-1}$ proteinase K before adsorption to hydroxyapatite. The hydroxyapatite eluate from the proteinase K-digested HSS contained a 10-fold higher titre than that of the undigested HSS, and a greater proportion of the total scrapie infectivity was inactivated with DNase (Table 1).

In support of the above findings, we have since succeeded in obtaining a purified preparation of scrapie agent of higher titre using ammonium sulphate precipitation of the HSS and separation of the resuspended precipitate by polyacrylamide gel electrophoresis⁹. Enzyme treatment of scrapie infectivity from these gels (Table 1), in conditions similar to those described for the treatment of the hydroxyapatite eluates, also resulted in a significant decrease in scrapie activity after exposure to DNase (100 $\mu\text{g ml}^{-1}$), but not to RNase A (100 $\mu\text{g ml}^{-1}$) or proteinase K (100 $\mu\text{g ml}^{-1}$).

These results show that as the heterogeneous infectious complexes in the HSS are separated, either by hydroxyapatite

chromatography or polyacrylamide gel electrophoresis, fractions of infectivity can be detected which are sensitive to treatment with DNase. It is, therefore, reasonable to conclude that the scrapie agent contains an essential DNA component. This finding is compatible with other studies^{3,10,11} which have detected low-molecular-weight DNA sequences in scrapie-infected brain, but which have been of questionable significance because of the inability to relate these nucleic acids to infectivity. However, the exact nature, size and possible association of this scrapie-specific DNA with other macromolecules requires further study.

We thank Alex Karu, Roland Rueckert and Howard Temin for discussions. These studies were supported by the College of Agricultural and Life Sciences, University of Wisconsin-Madison, and by NSF grant GB 39605 and NIH grant AI 11250.

Highly conserved DNA of Ti plasmids overlaps T-DNA maintained in plant tumours

LARGE tumour-inducing (Ti) plasmids in *Agrobacterium tumefaciens*¹ are responsible for crown gall disease in dicotyledonous plants^{2,3}. Plant tumour cells cultivated *in vitro* in the absence of the inciting bacterium maintain multiple copies of part of the Ti plasmid^{4,5}. The experiments presented here show that part of the Ti plasmid maintained in tumour cells (T-DNA) is highly conserved among diverse Ti plasmids.

Ti plasmids from a variety of natural isolates of *A. tumefaciens* exhibit only partial DNA homology^{6,7}. Their fingerprints, produced by cleavage of plasmid DNA with restriction endonucleases, are markedly different^{8–11}. Ti-plasmid-borne genetic traits (octopine and nopaline metabolism)^{2,3,12–15} suggest that Ti plasmids are of three types, and physical studies confirm this^{6–11}. Schell and his collaborators¹⁶ have suggested that since common tumour-inducing functions are a feature of every Ti plasmid, a region of homologous DNA should be detectable in all types. We have mapped the plasmid pTi-B6-806 (ref. 17) and located the T-DNA, the region of this plasmid that is maintained in E9 tobacco tumour (Fig. 1)^{4,18}. We report

Fig. 1 Map of *Sma*I, *Hpa*I and *Hind*III restriction endonuclease cleavage sites in part of pTi-B6-806. Evidence for the map order is given in detail elsewhere^{17,18}. Certain fragments of pTi-B6-806 used in this study were designated A-F as indicated above for clarity. Evidence for the boundaries of the DNA detected in E9 tumour (T-DNA) is presented elsewhere^{4,5,18}.

here DNA hybridisation studies that test this region of pTi-B6-806 for homology with six representative Ti plasmids.

A map of the sector of pTi-B6-806 that is relevant to this study is presented in Fig. 1. For the DNA hybridisation studies described below, pTi-B6-806 DNA fragments to be used as probes were isolated after preparative agarose gel electrophoresis of plasmid DNA digests⁴. Fragments were labelled by the 'nick translation' reaction¹⁹.

Figure 2 presents *Sma*I cleavage patterns of the Ti plasmids examined here. Nopaline-type plasmids are diverse, and are

Fig. 2 *Sma*I cleavage patterns of diverse Ti plasmids. Descriptions and sources of bacterial strains are detailed elsewhere¹⁰. Plasmid DNA (2.5 µg) isolated as described previously¹⁰ was adjusted to 0.02 M Tris, pH 7.5, 15 mM KCl, 6 mM MgCl₂ and treated with sufficient *Sma*I to give a complete digest in 2 h at 30 °C. *Sma*I was purified by the procedure of Lyle Brown, Oregon State University (private communication). Digests were subjected to horizontal slab gel electrophoresis¹⁰ and bands were visualised by staining for 20 min with ethidium bromide (10 µg/ml) and illuminating on a Blak-Ray Transilluminator (UV Products Inc.). Arrows above each digest indicate the positions of fragments that hybridised strongly (solid arrows) or weakly (dotted arrows) with *Hind*III fragments 1 and 5; the probe is indicated by the number above each arrow. The letters beneath each digest indicate the positions of fragments that hybridised with probes A-F, as defined in Fig. 1.

represented by pTi-223, pTi-C58, pTi-T37, pTi-AT181 and pTi-IIBV7. The only known null-type plasmid is pTi-542⁹. Octopine-type plasmids are highly conserved⁶⁻¹⁰ and are represented by pTi-B6-806, the homologous DNA control. On the basis of DNA homology measurements^{6,7} pTi-IIBV7 and pTi-542 are more closely related to the octopine-type plasmid than are any of the other plasmids studied here.

Digest fragments of Ti plasmids (Fig. 2) were transferred from the agarose gel to sheets of cellulose nitrate (Schleicher and Schuell, B6 membrane) by a modification²⁰ of the Southern blotting procedure²¹. Transfers were cut into longitudinal strips for hybridisation with various labelled DNA fragments.

*Hind*III fragment 1 labelled DNA hybridised with most of the heterologous plasmids extensively, as shown in the autoradiograms of Fig. 3 (data not shown for pTi-542). In four of the heterologous plasmid digests, the labelled DNA bound almost exclusively to a fragment of approximately the same electrophoretic mobility as *Sma*I fragment 10c of pTi-B6-806

Fig. 3 Autoradiograms of hybrids formed with labelled *Hind*III fragments 1 and 5 as probes. DNA fragments used as probes were labelled to specific activities of $1-50 \times 10^6$ c.p.m. per µg by incorporation of [α -³²P]thymidine triphosphate (90-150 Ci mmol⁻¹) or [α -³²P]deoxycytidine triphosphate (1,500 Ci mmol⁻¹) (NEN) using the nick translation reaction¹⁹. Cellulose nitrate transfer strips prepared from the gel of Fig. 2 or similar gels were allowed to hybridise with labelled DNA fragments (10⁵ c.p.m. per ml in 2.5 × SSC at 63 °C for 18 h) as described elsewhere (SSC is 0.15 M NaCl, 0.015 M trisodium citrate). The solid and dotted arrows above the bands indicate the intensity of hybridisation of the probes, and correspond to solid and dotted arrows in Fig. 2. Upper set of autoradiograms, *Hind*III fragment 1 probe. Lower set, *Hind*III fragment 5 probe.

(solid arrows marked 1 in Fig. 2). In the remaining two cases, pTi-IIBV7 and pTi-542, two fragments of higher molecular weight bound the labelled probe less efficiently. As expected from the map position of *Hind*III fragment 1 (Fig. 1), this probe hybridised strongly with pTi-B6-806 *Sma*I digest bands 3 and 10.

Thermal dissociation profiles of the DNA/DNA duplexes formed with *Hind*III fragment 1 probe are presented in Fig. 4. The *T*_m (midpoint of thermal dissociation) of homologous duplexes, 86 °C, is 3-5 °C higher than that of the heterodu-

Fig. 4 Thermal dissociation profiles of *Hind*III fragment 1 duplexes. The autoradiogram of the upper portion of Fig. 3 was used as a guide to locate bands of DNA duplexes corresponding to the solid arrows. The cellulose nitrate segment bearing these duplexes was excised and placed in a 10×75 mm test tube. The segment was eluted with 1 ml aliquots of 1×SSC at 22°, 60°, 65 °C and so on and radioactivity eluted at each temperature was assayed. Radioactivity eluted at 22 °C and that remaining on the cellulose nitrate segment at the end of the melt were negligible. Total radioactivity eluted was 1,500–2,000 c.p.m. in all cases. ▲, pTi-B6-806 ($T_m = 86^\circ\text{C}$); △, pTi-IIBV7 ($T_m = 81^\circ\text{C}$); □, pTi-223 ($T_m = 82^\circ\text{C}$); ●, pTi-CS8 ($T_m = 82^\circ\text{C}$); ○, pTi-T37 ($T_m = 82^\circ\text{C}$); ×, pTi-AT181 ($T_m = 82^\circ\text{C}$), ■, pTi-542 ($T_m = 83.5^\circ\text{C}$)

plexes, indicative of 3–5% base-pair-mismatching in the latter²⁴.

Labelled *Hind*III fragment 5 of pTi-B6-806 hybridised less extensively to all heterologous plasmids than to the homologous one (Fig. 3). The arrows marked 5 in Fig. 2 indicate the fragments that bound this labelled probe well (solid arrows) or poorly (dotted arrows). We have not examined in detail which part of *Hind*III fragment 5 is conserved in the heterologous Ti plasmids.

We obtained a more detailed picture of the extent of the conserved DNA region within and to the left of *Hind*III fragment 1 by using as labelled probes *Sma*I and *Hpa*I digest fragments of pTi-B6-806. The 42 autoradiograms from these experiments are not shown here, but the results are summarised in Fig. 2. The labelled probes are designated by serial letters A–F, corresponding to their left-to-right map order as indicated in Fig. 1. Probe A hybridised with only two heterologous plasmids, pTi-542 and pTi-IIBV7, at positions marked A in Fig. 2. In contrast to probe A, probe F hybridised efficiently with most of the Ti plasmids, but very poorly with pTi-542 and not detectably with pTi-IIBV7 (Fig. 2).

Probes B, C, D and E hybridised with all of the Ti plasmids examined, and must therefore constitute a region of DNA common to all (Fig. 2). This common DNA region extends on the map from *Sma*I fragment 17 to *Hpa*I fragment 14, a region of 5.5×10^6 daltons or less. Probe F (*Hpa*I fragment 13) could also be considered a part of the common DNA region, for its DNA sequences are preserved on most of the Ti plasmids examined. However, the region of conserved DNA indicated in Fig. 1 does not include this imperfectly conserved fragment. The T-DNA portion of pTi-B6-806 (Fig. 1) is at least contiguous with this conserved DNA element, and since the left boundary of T-DNA is not precisely known, it is possible that it overlaps the conserved DNA region. The T-DNA of a T37 tumour line under investigation in this laboratory contains all of this conserved DNA region from pTi-T37 (ref. 22).

If there have been no gross rearrangements of DNA in these plasmids during evolution, the results presented here predict

the serial map order of the heterologous Ti plasmid fragments to be the same as that of the pTi-B6-806 probe fragments A through F, to which they hybridise (Fig. 2). We have confirmed this order by conventional mapping techniques¹⁷ for pTi-T37 (ref. 23).

It seems reasonable to predict that crown gall tumour lines incited by bacterial strains carrying the heterologous Ti plasmids studied here will contain segments of those plasmids that are proximal to the conserved DNA sequences. The results presented here show, however, that a significant portion of the T-DNA of pTi-B6-806 comprises DNA sequences not common to all Ti plasmids. The right half of *Hind*III fragment 1 is not conserved, for all of the hybridisation of this probe is ascribable to probes E and F (Figs 1 and 2), which overlap its left end. The non-conserved part of the T-DNA may code for octopine production in pTi-B6-806, a trait not shared by nopaline-type Ti plasmids, which code for nopaline production by tumours^{1,9,13,14}.

The genetic evidence of Depicker *et al.*²⁵ in the accompanying paper indicates that the common DNA sequences analysed here do indeed code for functions essential to oncogenicity. This DNA could code for functions related to the process of transformation, or for functions required in the tumour cell for maintenance of the transformed state. Transcripts of Ti plasmid DNA have been detected in crown gall tumour tissue²⁶, but it is not clear whether the common DNA region of pTi-B6-806 is transcribed. Further evidence is needed for an understanding of the role of this highly conserved DNA element in crown gall tumour induction.

This research was supported by grant CA13015 from the NIH and grant NP194 from the American Cancer Society. D.J.M. was supported by a NSF postdoctoral fellowship. We thank Professor J. Schell and A. Depicker for useful discussions and exchange of data prior to publication.

Homologous DNA sequences in different Ti-plasmids are essential for oncogenicity

LARGE plasmids, called Ti-plasmids¹, are responsible for the transformation of dicotyledonous plants by *Agrobacterium tumefaciens*²⁻⁵. A comparison of Ti-plasmids derived from different *Agrobacterium* strains⁶⁻¹⁰ revealed two major groups of homology. These correlate with the Ti-plasmid-determined properties of octopine or nopaline utilisation by Ti-plasmid-harboring agrobacteria^{2,5,11-13}, and octopine or nopaline synthesis by Ti-plasmid-transformed plant cells^{11,13}. It was originally suggested that octopine or nopaline synthesis in crown-gall tissues might be mediated by bacterial genes, transferred to the transformed plant cells¹⁴; this can now be restated as being mediated by Ti-plasmid genes, and is supported both by genetic data¹⁵ and by hybridisation studies¹⁶. The capacity to determine both the catabolism and the synthesis of one or the other of these or similar compounds seems to be the dominant evolutionary significance of the Ti-plasmids and one can therefore speak of 'octopine'- and 'nopaline'- Ti-plasmids. In view of the fact that the different types of Ti-plasmids only have a limited degree of DNA sequence homology⁶, but produce transformed plant cells with similar phenotypes, it was conceivable that at least part of the common DNA sequences would be directly and/or indirectly involved in oncogenicity. We report here the finding of a specific DNA segment which is highly conserved among several different *Agrobacterium tumefaciens* Ti-plasmids. We also give genetic evidence that this region is essential for oncogenicity and overlaps with the Ti-plasmid DNA found in transformed plant cells.

The Ti-plasmid of strain ACH5 was used as an example of an octopine Ti-plasmid. This strain contains only one large plasmid (molecular weight 120×10^6), which was shown by heteroduplex analysis⁸ to be completely homologous to other octopine Ti-plasmids, such as the Ti-plasmid of strain B6S3. pTi-ACH5 DNA, isolated as described previously¹³ and radioactively labelled *in vitro* by nick translation¹⁸, was hybridised with the unlabelled DNA fragments obtained by digestion of the pTi-DNA from the nopaline strains C58 and K14 with various restriction endonucleases. Strong hybridisation was observed with only one segment of both nopaline Ti-plasmids. This segment was contained in one particular fragment of an *EcoRI* digest (fragment 1, MW 9.5×10^6), as can be seen for pTi-C58 DNA in Fig. 1. The largest band of the pTi-C58 *EcoRI* restriction pattern is, in fact, a doublet. After separation of the two fragments, it was demonstrated that the dominant hybridisation with pTi-ACH5 DNA was located in the *EcoRI*-1 fragment of pTi-C58 DNA. Other nopaline Ti-plasmids (from strains 223, T37, 396) were similarly tested for homology with pTi-ACH5 and it was found that they all contained an *EcoRI* fragment of MW 9.5×10^6 that showed a strong hybridisation with pTi-ACH5. This was particularly striking, as Ti-plasmids in avirulent mutant strains derived from strain K14 (ref. 15) did not exhibit this strong hybridisation.

Reciprocal experiments were carried out by hybridising total labelled pTi-C58 DNA with unlabelled DNA fragments of the octopine plasmid pTi-ACH5. Strong hybridisation was observed with the pTi-ACH5 *HindIII* fragment 1 (8.0×10^6 daltons) as can be seen in Fig. 1. These results thus indicated that this region is common to octopine and nopaline Ti-plasmids. Note here that various other fragments of these two types of Ti-plasmids exhibited a variable degree of hybridisation, as can be seen in Fig. 1, probably indicating a lesser extent of homology rather than an experimental artefact, as it was found that the extent of these hybridisations depended on the stringency of the hybridisation conditions used. Thus, it was found that in standard hybridisation conditions (see legend to Fig. 1), up to 80% of all the fragments of the pTi-ACH5 plasmid

Fig. 1 Homology between octopine and nopaline Ti-plasmids. Plasmid DNA was prepared from wild-type strains ACH5 and C58 (natural isolates), as described previously¹³. The restriction enzymes *EcoRI* and *SmaI* were purified in this laboratory. The conditions for digestion were 90 mM Tris, pH 7.5, 50 mM NaCl and 5 mM MgCl₂ for *EcoRI*, 15 mM Tris, pH 8.5, 15 mM KCl and 6 mM MgCl₂ for *SmaI* and 7 mM Tris, pH 7.5, 60 mM NaCl and 7 mM MgCl₂ for *HindIII*. The digests were separated in 0.8% agarose, formed in 40 mM Tris-acetic acid, pH 8, 20 mM NaAc, 1 mM EDTA and 0.5 µg ml⁻¹ ethidium bromide, on a horizontal slab gel apparatus²⁰. Fragments of decreasing molecular weight were represented by increasing numbers; only one number was given to single bands consisting of several fragments. The λ-*EcoRI* and λ-*HindIII* fragments were used as molecular weight standards. After electrophoresis (40 V, 16 h) and photographing of the restriction pattern²¹, the DNA fragments were transferred to a nitrocellulose filter (Schleicher and Schuell no. B6) according to the Southern blotting procedure¹⁷. By nick translation, the probe DNA was labelled with ³²P to specific activities of 1–30 × 10⁶ c.p.m. µg⁻¹, using [α-³²P]-guanosine triphosphate (Amersham, 350 Ci mmol⁻¹)¹⁸. After preincubation of the filters for 3 h at 75 °C in 2 SSC, containing 0.02% polyvinylpyrrolidone, 0.02% Ficoll, 0.02% bovine serum albumin (BSA) and 20 µg ml⁻¹ denatured salmon sperm DNA²², the denatured radioactive probe solution was added to the filters in a final concentration of 20 µg ml⁻¹. The filters were incubated for 24–40 h at 75 °C and were dried and exposed to X-ray film (Fuji films Rx Medical) after 4 or 5 serial washes (3 SSC, 0.5% SDS at 75 °C). The incubation temperature used in these experiments was therefore more stringent than the standard conditions used for the experiments shown in Figs 2 and 3, where the filters were incubated at 68 °C. A, pTi-ACH5 *HindIII* restriction pattern (lane a). Lane b represents the autoradiogram of the filter prepared from (a) and hybridised with ³²P-labelled pTi-C58 DNA. B, pTi-C58 *EcoRI* restriction pattern (lane c). Lane d represents the autoradiogram of the filter, prepared from (c) and hybridised with labelled pTi-ACH5 DNA. The numbers indicate the fragments showing the strongest hybridisation between the two types of plasmids.

Fig. 2 Characterisation of the homologous sequence between octopine and nopaline plasmids. The restriction digests, blotting of the DNA fragments to nitrocellulose filters and hybridisations were carried out as described in the legend to Fig. 1. A, pTi-C58: *EcoRI* (a), *SmaI* (c) and *HindIII* (e) restriction patterns, transferred to nitrocellulose filters and respectively (b, d, f) hybridised with the labelled pTi-ACH5 *HindIII* fragment 1 probe. This probe (pGV0201) was in fact a hybrid plasmid constructed by insertion of pTi-ACH5 *HindIII* fragment 1 in the vector pBR322 (ref. 23). B, pGV3505 (pTi-K14): *EcoRI* (a), *SmaI* (c) and *HindIII* (e) restriction patterns, transferred to nitrocellulose filters and respectively (b, d, f) hybridised against labelled pTi-ACH5 *HindIII* fragment 1 probe.

obtained by digestion with *HindIII* showed hybridisation with pTi-C58 DNA.

However, the stability of the hybrids formed by different regions varied considerably (data not shown). These results indicate that the two types of Ti-plasmids diverged from each other, conserving some regions more strictly than others.

To determine more precisely the extent of the homology in the fragments pTi-ACH5 *HindIII*-1 and pTi-C58 *EcoRI*-1, with which the dominant hybridisation was observed, the *HindIII* fragment 1 was cloned (G. De Vos *et al.*, in preparation), labelled and hybridised against the *EcoRI* restriction fragments of pTi-C58. As only the *EcoRI*-1 band of pTi-C58 became radioactive after hybridisation (Fig. 2), it must contain all the DNA homologous to the pTi-ACH5 *HindIII* fragment 1. Furthermore, hybridisation against *SmaI* and *HindIII* restriction fragments of the same pTi-C58 DNA indicated that the *HindIII* fragment 1 of the octopine Ti-plasmid was at least partly homologous to the *SmaI* fragments 5 and 7 (Fig. 2 A, c and A, d) as well as to the *HindIII* fragments 22 (2×10^6 daltons) and 31 (1.1×10^6 daltons) of the nopaline Ti-plasmid C58 (Fig. 2, A, e and A, f). *HindIII* fragments with an identical size and belonging to this conserved region were also found in pTi-K14 (Fig. 2 B, e and B, f) and pTi-T37. A more precise estimate of the size of this 'conserved' DNA sequence can be derived from the sum of the two *HindIII* fragments (together 3.1×10^6 daltons) of the nopaline Ti-plasmid, that hybridised with the pTi-ACH5 *HindIII*-1 fragment. A comparison of the physical maps of

octopine and nopaline Ti-plasmids in the region of the 'conserved' DNA segment (see Fig. 4) shows that the homology between the *HindIII* fragments 22 and 31 of the C58 pTi-plasmid and the *HindIII* fragment 1 of the ACH5 plasmid is restricted to the left end of this fragment. The remaining right part (4.9×10^6 daltons) of the pTi-ACH5 *HindIII* fragment 1 does not show any homology with the DNA of nopaline Ti-plasmids.

Fig. 3 Localisation of the RP4 integration site in the conserved DNA of the non-oncogenic pTi-C58::pRP4 cointegrate pGV4000. The restriction patterns and hybridisations were carried out as described in the legend to Fig. 1. The pTi-C58 and pGV4000 *EcoRI* (a,b) and *SmaI* (c,d) restriction patterns are shown in parallel to each other. In lanes a and c, the pTi-C58 fragment, in which RP4 is inserted, is indicated by its number. The composite fragment, provided by the junction between pTi-C58 and pRP4 DNA in pGV4000, are indicated by dashes. Lanes a and f, respectively, show the autoradiograms of the pTi-C58 and pGV4000 *HindIII* restriction patterns, which are transferred to nitrocellulose filters and hybridised with the labelled pTi-ACH5 *HindIII* fragment 1 and cloned in the vector pBR322 (ref. 23). The band indicated by an asterisk in lane e is the result of a partial digestion.

Fig. 4 Schematic representation of the conserved region in octopine (pTi-ACH5) and nopaline (pTi-C58) plasmids, showing the restriction map of the corresponding regions in both types of Ti-plasmid. Only those restriction sites used in the present analysis are shown. The cloning, detailed restriction map of the pTi-C58 *EcoRI* fragment 1 and the evidence for the precise localisation of the RP4 integration site in pGV4000 will be described elsewhere (M. De Wilde *et al.*, in preparation). The T-DNA is defined as that segment of the Ti-plasmid that has

been found integrated in the DNA of transformed plant cells. Arguments for the extent and localisation of the octopine T-region and for the relevant restriction map were taken from Chilton *et al.*^{16,24} and were adapted according to instructions from M.-D. Chilton. Arguments for the extent and localisation of the nopaline T-region were obtained in our laboratory and will be described elsewhere (De Beuckeleer *et al.*, in preparation).

The results described by Chilton *et al.*²⁴ indicate that the conserved region extends for another 3.5×10^6 daltons to the left of the *HindIII* fragment 1 of the octopine Ti-plasmids.

To discover whether or not this conserved DNA segment was involved in the oncogenic properties of the Ti-plasmids, we used our previous observations¹⁹, that the integration of a complete P-type plasmid pRP4 into the pTi-C58 plasmid can result in a loss of oncogenicity. Dissociation of the non-oncogenic pTi-C58::RP4 cointegrate (pGV4000) into its Ti and RP4 components resulted in a recovery of the oncogenic properties¹⁹. These observations can be explained if one assumes that pRP4 was reversibly integrated into a pTi-DNA segment that is essential for oncogenicity. The *EcoRI* and *SmaI* restriction fragment patterns of pGV4000 indicated that pRP4 had been integrated into the *EcoRI*-1 and the *SmaI*-7 fragments of pTi-C58 (Fig. 3).

To confirm that the integration of pRP4, resulting in a loss of oncogenicity, had occurred in the 'common' DNA sequence, the pTi-ACH5 *HindIII* fragment 1 was hybridised with the *HindIII* restriction fragments of pTi-C58 and pGV4000 DNA. Figure 3 e and f shows that the integration of pRP4 has occurred into the *HindIII* fragment 22 of the pTi-C58, as this fragment is absent and gives rise to two pTi-C58::RP4 composite DNA fragments. As this fragment 22 is completely homologous to the corresponding pTi-ACH5 DNA, one can conclude that RP4 has indeed been integrated into the conserved segment. A more precise mapping of the pRP4 insertion site (data not shown) has confirmed its localisation within the DNA region homologous to all Ti-plasmids tested so far (see also Chilton *et al.*²⁴). Figure 4 shows the position of the *SmaI*, *EcoRI* and *HindIII* fragments of pTi-C58 and pTi-ACH5 in the region of the conserved segment and the localisation of the pRP4 integration site in pGV4000. The T-region is defined as that segment of the Ti-plasmid that has been found integrated into the plant DNA. The extent and localisation of the 'octopine' T-DNA, determined by *Cot* analysis¹⁶ and the 'nopaline' T-DNA, determined by Southern hybridisation (M. De Beuckeleer, in preparation), can be seen in Fig. 4.

The results presented here indicate that different types of Ti-plasmids have a highly conserved DNA segment and that at least part of this conserved or common DNA segment is involved in determining the oncogenic properties of the Ti-plasmids, as the reversible integration of the pRP4 into this

conserved region results in the reversible loss of oncogenicity. The suggestion of the involvement of this conserved segment in oncogenicity is further supported by the finding that it borders and partly overlaps the regions of both the octopine and the nopaline Ti-plasmids (T-DNA) shown to be present in transformed plant cells¹⁶ (De Beuckeleer *et al.*, in preparation). Some of these results have been previously reported in a preliminary form^{10,15}.

We thank Dr M.-D. Chilton for discussions and for the exchange of data before publication, Jef Seurinck and Marc De Beuckeleer for the preparation of restriction enzymes and for technical assistance and Dr M. De Wilde for reading the manuscript. This work was supported by grants from the Kankerfonds van de ASLK and from the Fonds voor Kollektief Fundamenteel Onderzoek to J.S. and M. V.M.

Drug Action at the Molecular Level

Edited by G. C. K. Roberts

A collection of articles based on papers given at a Biological Council Symposium on Drug Action. The eminent contributors show how valuable the molecular approach can be in furthering our understanding of the physiological systems with which drugs interact, and of the relationship between chemical structure and biological activity.

A new approach in tissue culture

PETRIPERM

a novel culture dish
with gas permeable
membrane as cellular
support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents

PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.

In the intact animal, the pH and the partial pressure of both oxygen and CO₂ of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO₂, pCO₂ and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 µm thick membrane.

The laboratory ^{furniture} makers

Recently, somebody asked us if Morgan & Grundy make laboratory furniture!! Well, perhaps it's understandable.

Over the past few years, we've become so well known for our total laboratory planning, design and installation service – and for our unrivalled expertise in fume handling and in fume cupboard design and manufacture – that people tend to forget how Morgan & Grundy have been making and installing furniture in all types of laboratories all over the world for almost 50 years!

In fact, experience has led us to develop three distinctive furniture systems – Pedestal, Movable and Flexilab – all aesthetically pleasing yet robust and highly functional as well. All systems are available in a choice of steel, wood veneers or plastic laminate and; between them, they meet all conceivable needs in today's laboratories; both your own personal requirements and those of safety, durability, space economy and future re-planning.

In addition to the wide choice of basic systems and furniture types, Morgan & Grundy offer an infinite number of worktops, worktop materials, storage units, drying cabinets, titration units, desks, reagent shelves and service ducts – all designed with the object of reducing laboratory operating costs and increasing efficiency.

Our consultants will be only too pleased to discuss with you the Morgan & Grundy concepts of designed work stations and storage systems.

Different cap 1:cap 2 ratios in rabbit α and β globin mRNA

CAP structures type 0 ($m^7G^{5'}ppp^5X$), type 1 ($m^7G^{5'}ppp^5XmY$), and type 2 ($m^7G^{5'}ppp^5XmYmZ$), differing in the number of 2'-O-methylated penultimate nucleotides, have been found at the 5' termini of many viral and non-viral eukaryotic messenger RNAs¹. The ability to quantitatively remove the $m^7G^{5'}ppp$ -blocking group from eukaryotic mRNAs and to subsequently label their 5' termini with ^{32}P using [γ - ^{32}P]ATP and T_4 polynucleotide kinase has led to the determination of nucleotide sequences present at the 5' termini for rabbit α and β globin mRNA^{2,3} and alfalfa mosaic virus RNA 4 (ref. 4). The first six nucleotides of both rabbit α and β globin mRNA are identical and these two mRNAs each contain a mixture of cap types 1 ($m^7G^{5'}ppp^5m^6AmC$) and 2 ($m^7G^{5'}ppp^5m^6AmCmA$), differing only by the 2'-O-methylation of their penultimate C residues². This 5'-end labelling procedure can also be used to determine the relative amounts of cap types for each individual rabbit

print both on the basis of size and base composition². Further limited digestions of each 5'- ^{32}P -labelled T_1 -fragment with either pancreatic ribonuclease (cleaving only after pyrimidines and yielding ^{32}P - m^6AmCp and ^{32}P - $m^6AmCmAcp$) or T_2 ribonuclease (cleaving after both pyrimidines and purines and yielding ^{32}P - m^6AmCp and ^{32}P - m^6AmCmA) were carried out to determine the relative amounts of type 1 and type 2 cap structures present in each mature mRNA molecule.

Figure 1 shows a representative two-dimensional homochromatographic analysis of a pancreatic RNase digest of the ^{32}P - β -globin mRNA 5'-terminal T_1 -fragment purified as described above. The two distinct products which are clearly resolved in this system, ^{32}P - m^6AmCp and ^{32}P - m^6AmCmA , are separated on the basis of both size and base composition⁵. By similar analysis, a T_2 -RNase digest of the same β - T_1 -fragment also resolved two products, ^{32}P - m^6AmCp and ^{32}P - m^6AmCmA (data not shown). By quantitating the radioactivity present in each product, one can determine the cap 1:cap 2 ratio for an individual globin mRNA. The results from various preparations of rabbit α and β globin mRNA differing only in their relative recovery are summarised in Table 1. The cap 1:cap 2 ratio in three different mRNA preparations was consistently two- to threefold higher for rabbit α mRNA than for β mRNA. This result was independent of the relative quantities of α and β mRNA present in various preparations and the method used for separation and measurement of the T_2 or pancreatic digestion products. Also, these results did not reflect a difference in a potentially lower percentage of 5'-labelling of a type 2 cap structure by T_4 polynucleotide kinase due to the additional 2'-O-methylation⁶, as this would have been the case for both α and β mRNAs.

The significance of a two- to threefold enrichment of type 1 cap structures in mature rabbit α relative to β globin mRNA is

Table 1 Ratio of c.p.m. cap 1/c.p.m. cap 2 in [$5'$ - ^{32}P]-labelled rabbit α and β globin mRNA

Preparation	α/β	Analysis				Mean ratio cap 1/cap 2
		T_2 digest		Pancreatic digest		
		A	C	B	C	
I	0.53	α 515/230 (2.24)	—	—	—	2.24
		β 503/420 (1.20)	—	—	—	1.20
II	1.10	α 650/200 (3.24)	2,200/650 (3.40)	770/275 (2.80)	—	3.15
		β 440/320 (1.37)	—	440/295 (1.35)	700/660 (1.06)	1.27
III	0.35	α —	1,390/530 (2.62)	—	1,210/390 (3.10)	2.86
		β —	2,000/1,425 (1.40)	—	2,950/1,735 (1.70)	1.55

Limit digestion of ^{32}P -labelled α and β globin mRNA 5'-terminal T_1 fragments with either T_2 or pancreatic RNase were analysed as follows. A, Thin layer partition chromatography in isobutyric acid-concentrated NH_4OH-H_2O (66:1:33, v/v) (pH 3.7). B, Thin layer partition chromatography in 0.1 M sodium phosphate (pH 6.8) (100 ml) $(NH_4)_2SO_4$ (60 g), and *n*-propanol (2 ml) C, Two-dimensional homochromatography as described in Fig. 1. All three methods of analysis completely resolved both cap 1 and cap 2 structures from T_2 and pancreatic RNase digestions. Thin layer or homochromatography plates were autoradiographed and material detached from the glass by either scraping or removed as solid platelets using a solution of nitrocellulose⁷ and then counted in toluene scintillant⁵. α/β mRNA ratios were determined from counts present in both ^{32}P -labelled α and β 5'-terminal T_1 fragments purified by two-dimensional fingerprinting² of a T_1 RNase digest of unfractionated 5'- ^{32}P -labelled globin mRNA. There was reproducibly a direct correspondence between the relative amounts of radioactivity present in each 5'- ^{32}P -labelled T_1 fragment and the actual relative amounts of α and β globin mRNA present in each mRNA preparation as determined by polyacrylamide gel electrophoresis in both 7 M urea and 98% formamide². Differences in relative recoveries for α and β mRNA in various polysomal RNA preparations were due to procedural variations during phenol extraction of reticulocyte polysomes².

globin mRNA, without having to first purify each mRNA to homogeneity². In this work the cap 1:cap 2 ratios have been determined. The results indicate a two- to threefold enrichment of type 1 cap structures in α relative to β mRNA.

When a mixture of [$5'$ - ^{32}P]-labelled α and β globin mRNA was completely digested with T_1 ribonuclease, the individual α and β [$5'$ - ^{32}P]-labelled T_1 fragments were purified by two-dimensional fingerprintings². The α - T_1 -fragment (^{32}P - $m^6AmC(m)ACUUCUGp$) and the β - T_1 -fragment (^{32}P - $m^6AmC(m)ACUUCGp$) resolve from one another in the finger-

not clear. Results obtained by incubating erythropoietic mouse spleen cells with [methyl- ^3H]methionine have suggested that newly synthesised α and β globin mRNA may also exhibit similar cap ratio differences⁸. In the reticulocyte it has been estimated that each molecule of β globin mRNA initiates protein synthesis at a rate 30% faster than α mRNA⁹⁻¹¹. This difference is probably reflected in a difference in their nucleotide sequences at or near the region for initiation of protein synthesis. In this laboratory, it has been shown that there is a strict requirement for the integrity and presence of the m^7G

residue in the 5'-terminal cap structure for translation of rabbit globin mRNA both *in vitro* and *in vivo*¹². It has also been shown that β -eliminated vesicular stomatitis virus and reovirus mRNA have significantly higher rates of ribosome binding than corresponding unmethylated mRNAs in a reticulocyte lysate¹³. Whether the relative amounts of secondary 2'-O-methylations in normally capped α and β globin mRNA help determine their respective ribosome binding rates in the reticulocyte, however, is open to speculation.

In both mouse L cells¹⁴ and Novikoff hepatoma cells¹⁵, it has been shown that cap structures in cytoplasmic mRNA are derived from type 1 cap structures in heterogeneous nuclear RNA (hnRNA) from which a significant proportion is gradually converted to type 2 cap structures in the cytoplasm. Whether the observed differences in amounts of secondary 2'-O-methylations in rabbit α and β globin mRNA are therefore a reflection of their relative age or relative rates of mRNA turnover during erythroid development is currently under investigation. Recent experiments with mature mouse α and β globin mRNA also indicate similar cap 1:cap 2 ratio differences.

Fig. 1 Autoradiogram of a pancreatic RNase digest of the 32P- β globin mRNA 5'-terminal T₁-fragment. First dimension: cellulose acetate electrophoresis in pyridinium acetate buffer (pH 3.5) in 7 M urea. Second dimension: DEAE-cellulose TLC in 50 mM KOH strength 'homomix'⁵. The circled 'B' indicates the position of the xylene cyanole FF dye. Preparation of ³²P-labelled α - and β -globin mRNA 5'-terminal T₁ fragments was as described elsewhere². Pancreatic and T₂ RNase limit digestion conditions of these fragments and their subsequent analysis by two-dimensional homochromatography has also been described^{2,5}.

I thank Dr Uttam L. RajBhandary for laboratory facilities and Drs John K. Rose and Rajinder Ranu for reading the manuscript. This work was supported by grants from the NIH (GM17151) and the American Cancer Society (NP-114A) to U. L. RajBhandary. R.E.L. is a postdoctoral fellow of the Medical Foundation, Boston, supported by the Godfrey M. Hyams Trust and the Charles A. King Trust, and was a postdoctoral fellow of the Jane Coffin Memorial Fund for Medical Research.

The murine kappa light chain shift

THE immunoglobulins of mice and other animals consist of several distinct heavy chains associated with either of two light chains (κ or λ). Adult animals of different species produce immunoglobulins which demonstrate widely divergent ratios of κ to λ light chains. In mice, most of B-cell surface immunoglobulins possess κ light chains¹. However, as all previous work on the ratio of κ/λ immunoglobulins was based on experiments with adult animals, the possibility that immature populations of B cells may demonstrate a more evenly balanced ratio of κ to λ positive cells was investigated. In this study, populations of cells known to contain immature B lymphocytes were examined by indirect immunofluorescence for the presence of κ and λ positive cells. The results demonstrate that fetal liver, bone marrow and spleens from young mice contain B cell populations with a κ/λ ratio approaching unity. In the spleen, the κ/λ ratio increased as a function of age with the most dramatic shift occurring between 4 and 6 weeks of age. A similar, but less dramatic increase in the κ/λ ratio occurs in the bone marrow. Based on these data, we propose that the final predominance of κ -bearing cells is based on a two-stage process. Initially, there is an equal probability of κ or λ light chain expression at the cell surface. However, the κ -bearing cells, which possess a more abundant repertoire of V_κ genes, eventually predominate as a result of antigen driven clonal expansion.

Ontogenetic shifts occur between different heavy chain constant region (C_H) genes, allowing the association of the same V region genes with various C_H genes²⁻⁷. In all cases studied, these genes determining the various heavy chains exist in a single linkage group and share a common set of variable region (V_H) genes⁸⁻¹⁴. By contrast, the two classes of light chain, κ and λ , are determined by unlinked genes and each is associated with its own characteristic set of V genes¹⁵. There is, as yet, no evidence of any relationship between light chain class and physiological function or of any ontogenetic shift between λ and κ light chains. Hood *et al.*¹ have suggested that the predominance of κ or λ in a species is due to an evolutionary selection process in which a positive force has preferentially favoured one class of light chain.

It has been observed that the proportion of plasmacytomas and myelomas expressing κ or λ light chains in mice reflects the frequency of those light chains found in normal serum immunoglobulins^{16,17}. Further, it has been observed that the more abundant class of light chain in each species is associated with a greater number of V region subgroups, presumably reflecting a greater number of associated germ-line V genes¹⁶. These observations suggest that the imbalance in the κ/λ ratio is proportional to the number and diversity of the V region genes associated with each.

Here we present evidence that the expression of either κ or λ at the cell surface is a two-stage process. The initial choice between expression of κ or λ is based purely on random selection of an equal number of constant region genes. The preferential display of one or the other is then most likely based on antigen driven clonal selection, which in turn is

determined by the number of κ and λ V genes. Furthermore, we believe this selection force occurs during ontogeny, rather than as a phylogenetic event.

The percentage of cells in the spleen, bone marrow, and fetal liver which bear surface κ and λ light chains has been determined by indirect immunofluorescence. As shown in Table 1, the absolute percentage of Ig-positive cells increases in the spleen as a function of age; however, the ratio of κ - to λ -positive cells does not remain constant during this process. Initially, in the spleen of 1-week-old mice, the ratio (κ/λ) is 2.03, yet by 6 weeks of age this ratio has reached 6.59. The shift is not gradual as one might expect, but dramatically changes between 4 and 6 weeks of age. This shift seems to be T-cell independent in that the κ/λ ratio in adult nude mice does not significantly differ from normal adult mice (data not shown). By contrast, the κ/λ ratio in the bone marrow remains near unity until 1 yr of age when the value increases slightly. Similarly, the κ/λ ratio of Ig-positive cells in the fetal and newborn liver approaches unity. A plot of the κ to λ ratio in

the bone marrow and spleen as a function of age is shown in Fig. 1.

Statistical analysis of these data confirms the significance of the apparent increase in the κ/λ ratio (Table 2). In the spleen population, a clear pattern emerges. The κ/λ ratios of animals 1, 2 and 4 weeks old are not statistically different, however, the κ/λ ratios of the 6-week and 1-yr-old mice do differ from the 1-4-week-old groups. Although the κ/λ ratio in the spleen seems to increase again between 5 weeks and 1 yr, the difference was not significant ($P > 0.05$). The differences in the ratios of the spleen populations have been further confirmed by non-parametric Mann-Whitney U -sample and one-way analysis of variance testing (see Table 2, legend). The results from these statistical analyses and the apparent trend for the κ/λ ratio in the spleen to increase as a function of age (Fig. 1) support our hypothesis that the κ/λ ratio shifts during ontogeny as a result of some positive selection force, possibly antigenic stimulation. Analysis of the results from the bone marrow population also suggest an increase in the κ/λ ratio as a

* Indirect immunofluorescence was performed by a modification²¹ of the method of Pernis *et al.*²². Rabbit anti- κ chain serum (R $\alpha\kappa$) was from Bionetics and rabbit anti- λ chain serum (R $\alpha\lambda$) was provided by Dr James D. Folds (UNC, Chapel Hill). Polyspecific rabbit anti-mouse immunoglobulin serum (R α Mlg) was produced as described previously²³. Fluorescein-conjugated goat anti-rabbit Ig was from Meloy Laboratories. All antisera were used at a dilution of 1:40 in PBS-0.05M Na₂S₂O₅. Controls for phagocytosis and nonspecific adherence of Ig consisted of cells incubated only with the second antiserum or by using normal rabbit serum in place of the primary antiserum. These were consistently found to be negative (<2%). Results are expressed as % cells positive for surface fluorescence/total nucleated cells counted (>200). Mice of the C57BL/10ScSn and CBA/J background were used. As there was no apparent strain differences all data were pooled for analysis.

† A 'pool' consisted of the spleens, thymuses, or bone marrows of 4 animals which were combined in order to obtain sufficient cells to perform the assay.

‡ Mean $\pm$ standard deviation and range of percentages obtained from determinations for each cell population. ND, not determined.

Spleen and bone marrow cells from mice of various ages were assayed for % κ -positive and % λ -positive cells and κ/λ ratio was computed for each observation. For statistical analysis, the mean of the individual κ/λ ratios was determined for each age category. This convention was chosen since comparing the ratios of means is a less well-established procedure for this type of multi-level experiment. For parametric testing it is assumed that these observations are normally distributed as there is no apparent reason to indicate otherwise. Results from the paired contrast *t* test²⁴ are presented above. Results were also tested for significance by one-way analysis of variance (ANOVA)²⁴ and non-parametric Mann-Whitney *C*-sample testing²⁵. On ANOVA testing, the means of the κ/λ ratios in the different age categories of the spleen were found to be statistically different (*P* < 0.001). Similarly when tested by the more conservative non-parametric Mann-Whitney *C*-sample test, these ratios were also found to differ (*P* < 0.001). Although the paired contrast *t* test demonstrates significance for the different age groups in the bone marrow, the means of the bone marrow age groups were not different (*P* > 0.05) when tested by ANOVA and Mann-Whitney *C*-sample testing. Further, it should be noted that these cell populations do not demonstrate homoscedasticity (equal dispersion within age categories), thus the results from these statistics may be affected by failure to comply with this assumption.

* Mean of the individual κ/λ ratios ± s.d.

† Not significant at α = 0.05.

function of age. When the means of the ratios for the different age categories were compared by paired contrast *t*-testing, the 2, 4 and 6-week-old groups were not different, however the 1-yr-old group was found to be different from the 2 and 4-week-old groups. Unlike the results obtained with the spleen populations, we were unable to confirm the significance of the changes in the bone marrow with one-way analysis of variance and non-parametric Mann-Whitney *C*-sample testing. Despite these limitations, a general trend towards an increasing κ/λ ratio is seen in the bone marrow as a function of age, suggesting a κ/λ shift occurs which is similar to, but less dramatic than, the shift seen in the spleen.

Fig. 1 Shift in κ/λ ratio in murine B lymphocytes with age.

Barandun *et al.*¹⁸ have also reported a slight but significant shift in the κ/λ ratio in normal human serum immunoglobulins as a function of age. Also similar to our findings, Spear *et al.*¹⁹ have shown a near doubling in the percentage of Ig-positive Swiss-L mice spleen cells between 2 and 4 weeks of age. Coincident with the increase in B cells, they noted an onset of the capacity to respond to antigens and a significant increase in the ratio of B to T lymphocytes. These events are thought to occur as a result of, rather than the cause for, immunological competence.

Based on these data, we propose that prior to an antigen driven selection process the probability of a cell expressing

surface κ or surface λ is equal. The nearly equal proportion of κ - and λ -positive cells in the populations which contain immature B cell precursors (bone marrow and fetal liver), strongly supports this hypothesis. Between 2 and 4 weeks of age an overall increase in the percentage of Ig-positive spleen cells occurs, yet the relative κ/λ ratio remains essentially the same. However, between 4 and 6 weeks of age, this ratio increases significantly (Table 2). This event may be due to the onset of immunological competence in the animal, allowing the selective clonal expansion of κ -bearing B cells. Molecular studies of immunoglobulin diversity also support this idea. In mice, which have so many more *V* genes associated with and available as partners to the κ *C* gene, the probability that they can collaborate with *V_H* genes to provide a good 'fit' for antigen is high¹⁶. Thus, during maturation, exposure and response to antigens will favour the expansion of the clones of cells expressing κ light chains.

As a corollary to our hypothesis, we would predict that the examination of spleen cells of adult gnotobiotic mice would show a κ/λ ratio significantly different from their normal littermates (that is, closer to unity). Furthermore, it may be possible to shift the κ/λ imbalance prematurely by deliberate immunisation of 2–3-week-old mice. Data from such experiments have proven suggestive, but not significant. The injection of a few exogenous antigens may be inconsequential in relation to the vast array of endogenous and environmental antigens 'seen' by the animal when immunological competence occurs.

The stimulus for this study was the observation that two recently discovered murine B-cell lymphomas were both found to express λ light chain associated with their surface IgM²⁰. This seemed to be most unlikely, on the basis that only about 5% of mouse immunoglobulins express λ chains and only very few murine myelomas have λ light chains^{16,17}. However, other cell surface characteristics (the absence of IgD and C'3 receptors) suggested that both tumours had been derived from a population of cells early in the ontogenetic pathway of B cells²⁰. Thus, we were led to examine other populations of immature B cells. Having done so, it seems that the initial selection made during maturation is between κ and λ *C* genes, and that only later do *V* genes become influential (that is, at

the time of onset of immunological competence). As a result, we further predict that in all species, the proportion of malignancies of 'early' B cells expressing surface κ or λ light chains will approach unity.

We thank Dr W. D. Kalsbeek for his help with statistical analyses and K. Mohr for assistance in production of mice.

Comparison of the evolution rates of cytosolic and mitochondrial aspartate aminotransferase

TWO isoenzymes of aspartate aminotransferase (AAT) occur in animal and possibly in all eukaryotic cells, one in the cytosol (cAAT) and the other in the mitochondria (mAAT)¹. Both isoenzymes are composed of two identical polypeptide chains of about 400 amino acid residues and their reaction mechanisms and kinetic features are essentially the same^{1,2}. They are homologous proteins, as evidenced by 48% sequence identity of the two isoenzymes from pig^{3,4}, and are both coded for by nuclear DNA and synthesized by cytosolic ribosomes⁵⁻⁷. Comparison of the isoenzymes from pig with those from chicken by quantitative microcomplement fixation has shown that the interspecies similarity of the mitochondrial isoenzymes markedly exceeds that of the cytosolic isoenzymes⁸. The same conclusion has been reached by comparison of the known amino acid sequences of the pig isoenzymes^{3,4} with the chicken isoenzymes, for which more than half of their sequences have already been determined. The sequence identity of the two cytosolic isoenzymes seems to be approximately 50% (Y. M. Torchinsky, personal communication), whereas that of the two

Fig. 1 Evolution of cytosolic (a) and mitochondrial (b) AAT. The mean immunological distances between the reference enzymes from pig and from chicken and the respective isoenzymes from the indicated vertebrate classes or orders are plotted against the palaeontologically estimated times of divergence of the ancestors of the reference species pig and chicken from the various vertebrate classes or orders. Immunological distances are taken from Table 1 and are not corrected for multiple mutations at the same site. To join the lines of the cytosolic pig and chicken enzyme in a at the point of their divergence 300 Myr ago, the line of the porcine enzyme was translated vertically by +53 immunological distance units. This translation distance was determined as the difference between the immunological distance of mammals and birds (mean of the reciprocal crossreactions 200 units) and the interpolated value of the line of the chicken enzyme at 300 Myr (117 units). The assumed times of divergence are¹³, in Myr: fishes, 400; amphibians, 340; birds and reptiles from mammals, 300; birds from reptiles, 240; interordinal divergence of placental mammals, 70; interordinal divergence of birds, 70; pig from the other artiodactyls, 60. The slope of the lines corresponds to the double value of the rate of evolution because the immunological distance measured is the sum of the changes accumulated by the 2 species compared since divergence from a common ancestor. The slope of the line of cAAT is 0.39 ($r = 0.95$) throughout the vertebrate classes except for mammals, where the slope is 0.97. For mAAT, the slope is 0.39 ($r = 0.96$) and 0.36 ($r = 0.98$) when measured with anti-mAAT_{pg} antiserum and with anti-mAAT_{chicken} antiserum, respectively.

mitochondrial isoenzymes is about 85% (ref. 9 and U. Hausner, P. C., K. J. Wilson, unpublished). In the present study, the immunological interspecies comparison of the two isoenzymes was extended to species of all vertebrate classes. The evolution of the two compartmented isoenzymes was found to have proceeded at identical and constant rates throughout the development of the nonmammalian vertebrates. After the emergence of mammals, however, the rate of evolution of the cytosolic isoenzyme more than doubled while its mitochondrial counterpart retained the slower rate of the nonmammalian vertebrates.

Table 1 Immunological distance between cAAT and mAAT from pig and chicken and the respective isoenzymes from species of all vertebrate classes

Species (source of extract)	Immunological distance between reference enzyme and respective isoenzyme from the indicated species			
	cAAT _{pig}	mAAT _{pig}	cAAT _{chicken}	mAAT _{chicken}

The immunological distance between the reference antigens (isoenzymes from pig and chicken purified to homogeneity) and the corresponding isoenzymes of the tested species were measured by quantitative microcomplement fixation as reported previously⁸. In pig and chicken the immunological distances obtained with heart tissue extracts were the same as those determined previously with the isolated enzymes⁸. No crossreactions between isolated cAAT and mAAT from either pig or chicken were observed. Thus, heart tissue extracts were tested without separating the two isoenzymes. Heart tissue was frozen not later than 3 h post mortem and stored at -20°C . The thawed tissue was homogenised with a Duall homogeniser in 5 volumes of the buffer used for the complement fixation, and centrifuged at $2,000g$ for 15 min. The extent of complement fixation at different concentrations of antiserum was determined at serial dilutions of the homologous and the heterologous antigen. A plot of the peak heights of the complement fixation curves against the logarithm of the antiserum concentration yielded a straight line. The lines of the crossreactions of a given antiserum with heterologous antigens were essentially parallel to the line obtained for the homologous reaction. The immunological distance (ID) was calculated according to $ID = 100 \log$ (antiserum concentration for 50% complement fixation with the heterologous antigen/antiserum concentration for 50% complement fixation with the homologous antigen) (refs 8, 10). Both anti-mAAT antisera crossreacted with rabbit heart extract as judged by quantitative microcomplement fixation and the Ouchterlony double-diffusion test. The crossreacting antigen from rabbit heart showed the same electrophoretic mobility in immunoelectrophoresis and the same molecular weight as mAAT from pig and chicken (determined by polyacrylamide gel electrophoresis in sodium dodecyl sulphate after extraction of the antigen-antibody complexes with *Staphylococcus aureus* carrying protein A). Thus, it is very likely that the immunisation with either heterologous mitochondrial isoenzyme had resulted in the production of antibodies against the rabbit's own mAAT. Similar breakage of the immunological tolerance has been reported for α -fetoprotein¹¹. In the present instance, this phenomenon might be related to the sequestration of the antigen in the mitochondria. The crossreactions in quantitative microcomplement fixation between the rabbit mAAT and the rabbit antisera against mAAT from pig and chicken are weak, corresponding to an immunological distance of 211 and 206, respectively. These crossreactions reflect an increase in antigenicity of the mitochondrial isoenzymes, that is, a larger surface portion surveyed by the antibodies, which may be expected to increase the reliability of the immunology sequence relationship¹². No reliable crossreactions were obtained from anti-cAAT_{pig} antiserum and the fish heart extracts.

Antisera to cAAT and mAAT from both pig and chicken were produced as described previously⁸. The degree of immunological crossreactivity of these reference antisera with the respective isoenzymes from representatives of all vertebrate classes was determined by quantitative microcomplement fixation and was expressed in terms of immunological distance (Table 1). Remarkably, the immunological distances between cAAT_{pig} and cAAT from all other species are substantially larger than those between mAAT_{pig} and mAAT from the other species. Similarly, the immunological distances between cAAT_{chicken} and cAAT from mammalian species are twice as large as the corresponding immunological distances obtained for mAAT_{chicken}. In contrast, the same immunological distances were obtained when cAAT_{chicken} and mAAT_{chicken} were compared with the corresponding isoenzymes from the non-mammalian vertebrate classes. The temporal course of the evolution of the cytosolic and the mitochondrial isoenzymes is reconstructed in Fig. 1a and b, respectively. The plots of the immunological distances against the times of divergence of the phylogenetic lineages show a constant rate of change for mAAT throughout all vertebrate classes. A constant rate of the same magnitude applies also to cAAT in all nonmammalian vertebrates. However, during the development of mammals, the evolution of the cytosolic isoenzyme proceeded more than twice as fast, indicating that an increase in the rate of change had occurred after the mammals had diverged from the common ancestor of reptiles and birds. This acceleration of the rate of evolution as found with the anti-cAAT_{pig} antiserum is confirmed by the reciprocal reactions with anti-cAAT_{chicken} antiserum (see Table 1).

For a set of homologous variants of a given protein, the immunological distance (ID) has been found to correlate linearly with the percentage amino acid sequence difference (Δaa) according to the equation $ID = 5 \times \Delta aa$ (refs 14, 15). For cAAT, the average time required for a 1% change in the amino acid sequence to arise between two genealogical lineages can thus be estimated to be 6 Myr in mammals and 12 Myr in the other vertebrates. The latter estimate also obtains for mAAT throughout the phylum of vertebrates. The values lie within the range found for other intracellular enzymes¹⁶. On the basis of these rates of change, the gene duplication underlying the development of the mitochondrial and the cytosolic isoenzyme (amino acid sequence difference in pig, 52% (ref. 4)) may be assumed to have taken place about 600 Myr ago, at the time of the emergence of the vertebrates. This indicates that the isoenzymes of the vertebrates do not originate from the same gene duplication that gave rise to the isoenzymes found in fungi¹⁷ and plants¹⁸.

Changes in the rate of evolution of certain proteins such as globin chains¹⁹ or lysozyme/lactalbumin²⁰ have been reported, but such changes have been questioned¹⁶. However, the main argument against these cases, that of the uncertainty in estimating the time of interspecies divergence, does not seem pertinent to aspartate aminotransferase. The increase in rate is found specifically with the cytosolic isoenzyme, whereas the closely related mitochondrial isoenzyme retains the slower rate of evolution. Thus, the conclusion that the cytosolic isoenzyme changed its rate of evolution is warranted independently of the palaeontological time scale.

The increase in the rate of evolution of the cytosolic isoenzyme in mammals may be due to positive natural selection towards an improved, newly developed function of the isoenzyme or may reflect the loss of an obsolete noncatalytic function. The cause of the change in the evolution rate remains open to conjecture. The fact, however, that the crucial difference between the two compartmented isoenzymes exists only in mammals might facilitate its eventual identification. Data soon available on the primary and spatial structure of both isoenzymes²¹⁻²³ will enable the comparative study of the evolution of their structural and functional features, thus providing an informative approach to the study of the interrelationship of function and evolution of proteins.

Structure of DNA predicted from stereochemistry of nucleoside derivatives

CRYSTALLOGRAPHIC data on the constituents of nucleic acids can be very useful in predicting secondary structures. Until recently only data from the crystal structures of mononucleosides and mononucleotides have been used in building models of secondary structures for nucleic acids and polynucleotides. However, such data only provide information about the stereochemistry of nucleosides and not the relative orientation of the nucleotides around the 3' and 5' phosphodiester bonds. This relative orientation is the key factor which determines the secondary structure of nucleic acids and details of this orientation can be obtained from single-crystal study of dinucleoside monophosphates and other higher oligomers. So far, crystal structure data on the dinucleoside monophosphates GpC (sodium salt)¹, GpC (calcium salt)², ApU³, UpA⁴, a dinucleotide pTpT⁵, a trinucleoside diphosphate ApApA⁶, and a tetranucleotide pApTpApT (M.A. Viswamitra, personal communication) are available. We have analysed the conformations of these molecules and present here stereochemical criteria for the backbone of the polynucleotide chains and the nucleic acids. Application of these criteria to nucleic acids indicates type II structure for DNA, as proposed previously by us⁷ as an alternative to the double helix.

Table 1 lists in the alphabetical notation the torsion angles of the sugar phosphate backbone of dinucleoside monophos-

* Deoxy sugar.
† M. A. Viswamitra, personal communication.
‡ Present work.

phates and similar fragments in higher oligomers³; row 2 shows the respective bonds about which the torsion angles are measured. The sugar and nucleoside parts of these dinucleoside monophosphate fragments have conformational features similar to those of mononucleosides and nucleotides⁸. Thus

puckering of the sugar is either in the C3' *endo* or C2' *endo* region. The conformation about C5'-O5' is *trans* (*t*) and about C4'-C5' is *gauche-gauche* (*gg*). The major degrees of conformational freedom responsible for the orientation of the adjacent nucleotide units are about the phosphodiester bonds and accordingly these fragments have been grouped into three sets. Sets I, II and III have, respectively, the conformation *g⁻g⁻*, *tg⁻*, *g⁺g⁺* about the P-O bonds.

In sets I and II, γ varies from 271° to 302°, whereas β varies from 283° to 293° in set I and 163° to 168° in set II. In set III both β and γ are restricted from 76° to 92°. Thus for β , the observed conformations correspond to *g⁻*, *t*, *g⁺*, whereas for γ , they are *g⁻* and *g⁺*. The other torsion angle α varies from 204° to 224° except in TpT where it is 252°. Conformational energy calculations^{9,10} also indicate that *tg⁻*, *g⁺g⁺* conformations about the P-O bonds observed in the crystal structures are energetically as favourable as the *g⁻g⁻* conformation. The above conformational criteria of the backbone of the dinucleotide fragments have been used to predict possible secondary structures for polynucleotide chains.

Taking into account the conformational flexibility about the phosphodiester bonds and the possible variations in the remaining torsion angles, the conformational features of regular helical polynucleotide were analysed, using average bond lengths and bond angles for the monomer unit. Both right- and left-handed double helical structures with Watson-Crick base-pairing schemes were studied. The details of the calculations and the results will be reported elsewhere. Here, we discuss first the single chain helical parameters *n* and *h* (*n* is the number of nucleotide residues per turn and *h* the height per residue) which are relevant to the conformation of double stranded polynucleotides. As stated above, the major degrees of conformational freedom and the key to the conformation of nucleic acids are about the P-O3'(β) and P-O5'(γ) bonds. The salient features of the results are therefore presented in the β - γ space keeping other torsion angles fixed (Fig. 1). Although the crystal data given in Table 1 suggest only *gg* conformation about the C4'-C5' bond, we have also considered *gt* and *tg* conformations about this bond to determine the sensitivity of

Fig. 1 Helical domains in the β - γ space corresponding to the conformations *gg*, *gt* and *tg* about the C4'-C5' bond, for C2' *endo* (solid line) and C3' *endo* (dashed line) sugar pucker. Only *n*=8 and *h*=0 are shown. Right and left helical sections are denoted by R and L.

the helical parameters with these conformations. The results are shown for two representative values of ζ , 90° and 140° ; the former in the C3' *endo* region and the latter in the C2' *endo* region. Interestingly the helix forming domains shown in Fig. 1 contain both right- and left-handed helices, and small changes in the values of β and γ alter the sense of the helix. Also the helix that forms domains in the β - γ space is sensitive to the sugar puckering and the conformation about the C4'-C5' bond. Thus a change in ζ from 90° to 140° produces a shift in β from g^- to t . Thus a change in the conformation about the C4'-C5' bond also produces a corresponding change in the conformation about γ . If the conformations about the C4'-C5' bond are gg , gt and tg , then in the helical domains the corresponding conformations about the P-O5' bond are g^- , t and g^+ respectively.

The observed conformation about the C4'-C5' bond is gg , so the helical domains in the β - γ space will be restricted to g^-g^- and tg^- . These are precisely the conformations about the P-O bonds that are observed in the crystals and given under sets I and II of Table 1. When g^+g^+ conformations of set III are used, no regular helical polynucleotide structures can be generated^{11,12}. But these conformations in the middle of a polynucleotide can reverse the chain direction¹³. In other words, g^+g^+ conformations about the P-O bonds can lead to a fold or bend along its backbone. Besides, in the case of a helical polynucleotide, the g^+g^+ conformation in the middle can change the handedness of the helix. We have used this conformation in the bend region of the type II model for DNA⁷.

Set IV in Table 1 lists the backbone torsion angles of right-handed double helical structures for nucleic acids reported in the literature¹⁴⁻¹⁸ for comparison with the crystal data. The agreement between A-RNA¹⁴ and the crystal data is very good. In contrast the agreement between the various conformations of DNA and the observed data is not good. In fact, the agreement is poor for both B and D DNA^{16,18}— α is much lower than the lowest observed value. Also, angles β and δ in B DNA and β in D DNA are different from the observed values.

To establish the conformational angles of the backbone for different forms of DNA which are close to the observed angles, helical domains were computed in the α - β space keeping γ , δ

Fig. 2 Helical domains in the α - β space for C2' *endo* puckering ($\zeta = 140^\circ$). n (solid line) and h (dashed line) contours and observed torsion angles α and β of the fragments with C2' *endo* puckering for the sugar are shown. R and L denote right- and left-handed B DNA

and δ fixed in their respective average values (Table 1). The helical domains (also n and h contours) thus obtained for the average values of ζ in the C2' *endo* and C3' *endo* regions are given in Figs 2 and 3. The α , β values given under sets I and II are also plotted in these figures to show roughly the type of helical structures that will be generated for these fragments.

As before, the $h = 0$ contour divides the helical domains into right and left helical sections, and an iso- h contour cuts an iso- n contour at two places. Thus, as shown in the diagram, four regions, R_I and R_{II} in the right and L_I and L_{II} in the left helical sections are possible for single chains. For a given n and h value, in each helical domain two right and two left helical

Fig. 3 Helical domains in the α - β space for C3' *endo* puckering ($\zeta = 90^\circ$). n (solid line) and h (dashed line) contours and observed torsion angles α and β of the fragments with C3' *endo* puckering for the sugar are shown. For GpC (Ca) the plotted conformation refers to the average values of the four independent molecules in the crystal.

structures are possible. However, not all of them lead to double helical structures with Watson-Crick base pairing.

In the C2' *endo* case shown in Fig. 2, the observed conformations ApT(1) and ApT(2) have very small n values and hence double helices are not possible. TpA and TpT lie in the L_{II} regions. In both these regions the bases are away from the helix axis and hence base-paired double helical structures are again not possible. Thus, double-helical structures are not generated when one uses the observed backbone conformational angles in the C2' *endo* region.

In the R_I and L_I regions, however, the bases overlap and hence double helical structures are possible. In fact by allowing the variations that are observed in the remaining torsion angles one can construct a series of stereochemically feasible right- and left-handed double helical structures consistent with the helical parameters of B DNA. The values of α and β for a left-handed double-helical structure with the B DNA parameters which we have constructed are plotted in Fig. 2 together with those for the right-handed helical structure¹⁶. We are now investigating whether X-ray fibre diffraction data could be used to distinguish between left-handed and right-handed models which have conformational angles as close as

possible to those observed in the crystals. The only remaining conformational angle χ about the glycosidic bond has a value near 0° for the left-handed structure while $\chi \approx 75^\circ$ for the right-handed structure, as reported previously⁷.

In Fig. 3, for the C3' *endo* case, except UpA and TpA, the other observed conformations are clustered in R₁ with $n = 8$ to 11 and $h = 2$ to 3 Å. Thus double helical structures can indeed be generated with the observed backbone conformational angles in the C3' *endo* region. In the case of both L_I and L_{II} regions, the bases overlap, so double helical structures are possible.

Thus for the *gg* conformation about the C4'-C5' bond, the helical domains occur in the β - γ space at the g^-g^- and tg^- regions, which are precisely the observed regions of conformations for the fragments given. Small variations in dihedral angles bring about changes in the sense of the helix and both right- and left-handed double helical structures are possible. It is clear that conformations similar to the fragments in sets I, II and III can lead to right helical, left helical and bend (or fold) structures respectively. A structural model for B DNA can thus be constructed with right and left helical segments having backbone conformations similar to sets I and II respectively. Conformations similar to set III serve to link consecutive right and left segments of a chain. A structure thus arrived at is a type II structure proposed previously by us⁷ as an alternative structure for DNA. The type II structure is not a double helix but consists of a pair of polynucleotide strands held together by Watson-Crick base pairing. Each of the two strands has alternating right- and left-handed segments approximately five base pairs long. As a consequence of mixing right-handed with left-handed helical segments and vice versa, each strand has bends or folds. These bends impart a significant amount of flexibility to the polynucleotide. This inherent flexibility of the type II structure can permit the initiation of the supercoiled structure of DNA following energetically allowed folds. This flexibility along the backbone could provide a possible solution to the compression of DNA within chromatin¹⁹.

We thank Professor M. A. Viswamitra for conformational data on pApTpApT. This work was supported by a grant from the Department of Science and Technology, Government of India. N.P. thanks the University Grants Commission for financial assistance.

Corrigendum

In the article 'Decision making in animals' by D. J. McFarland, *Nature* **269**, 15 (1977), the sentence starting in line 16 on page 18 should read: On this basis we can express the expected probability of fertilisation, given that the male is still involved in the courtship as

$$\varepsilon \int_0^T [u_1(t) + e^{\varphi S(t)} u_3(t)] S(t) x(t) dt.$$

Also on page 18, the scheme based on Dempster's formulation (ref. 14) should read as shown below:

Objective: Maximise likelihood of successful fertilisation

$$\int_0^\infty \{ \exp [-\varphi S(t)] S(t) u_1(t) x(t) + S(t) u_3(t) x(t) \} dt$$

Plant equation: $\dot{x}(t) = -x(t)^{-\rho} u_2(t) + \theta$

Work during courtship: $\frac{u_1(t)}{\delta} + \frac{u_2(t)}{\gamma} + \frac{u_3(t)}{\tau} \leq 1$

Energy expended during courtship:

$$\int_0^\infty \left[\frac{u_1(t)}{\delta} + \frac{u_2(t)}{\gamma} + \frac{u_3(t)}{\tau} \right] dt \leq E$$

Hamiltonian:

$$H = e^{-\varphi S(t)} S(t) u_1(t) x(t) + S(t) u_3(t) x(t) - F(t) \left[-x(t)^{-\rho} u_2(t) + \theta \right]$$

(Costate) Hamiltonian equation:

$$\dot{F}(t) = \frac{\partial H}{\partial x} = e^{-\varphi S(t)} S(t) u_2(t) - \rho \frac{F(t)}{x(t)^{1+\rho}} u_2(t) + S(t) u_3(t)$$

states: S = spermatophore count (0-3)

x = oxygen 'debt'

controls: u_1 = rate of display behaviour (maximum rate δ)

u_2 = rate of creep behaviour (maximum rate γ)

u_3 = rate of spermatophore transfer (maximum rate τ)

parameters: φ = basic discount rate of display behaviour
 ρ = control parameter for rate of decrease of x through skin respiration during creep behaviour

θ = rate of increase of oxygen debt with time (during display and transfer behaviour)

E = maximal energy expended in courtship

F = costate variable = marginal value of likelihood of success per unit of x

Nature Index and Binders

The complete **Index** for 1977 is available, price £2.50 (UK), US\$5.00 (Rest of World). Copies of the 1976 index are still on sale, prices as above.

Binders for the journal are also available at £8.00 (UK), US\$16.00 (Rest of World) for three: a year of *Nature* fits into three binders.

All prices include postage. Payment may be made in any currency at the prevailing exchange rate. Orders should be sent, accompanied by remittance, to Macmillan Journals Ltd, Brunel Road, Basingstoke, Hampshire, RG21 2XS, UK.

IMMUNOPHARMACOLOGY

An international journal
combining the fields of immunology and pharmacology.

Editor-in-Chief: **Dr. J.R. Battisto**, *Department of Immunology, Cleveland Clinic Foundation.*

Combining the fields of immunology and pharmacology, this journal will provide a medium for the publication of full-length articles and short communications in the following areas:

- The action of hormones and their mediators; e.g., cyclic nucleotides, prostaglandins in the regulation of the function of cells participating in immune responses.
- Hormones and cell factors endogenous to the immune system that are bioregulatory for lymphocyte and macrophage maturation, differentiation and replication.
- Cellular components that assist in regulating the functioning of cells synthesizing antibodies, cells mediating cellular killing and cells controlling immunological unresponsiveness.
- Mediators of immediate and delayed-type hypersensitivities.
- Pharmacological substances used as probes into molecular and cellular events involved in immunological responses.
- Items released through immunological and closely related pathways that are pharmacologically active at non-immunological levels.
- Factors useful for prevention, prediction and diagnosis of clinical entities, such as carcinomas, autoimmune diseases and immunological deficiencies.
- Viral and gene products operative in immunopathology.

Coming to terms with Nature

Eric Ashby

The Twenty-Ninth Day: Accommodating Human Needs and Numbers to the Earth's Resources. By L. R. Brown. Pp. 363. (Norton: New York, 1978.) \$11.95.

THE title of this book is another example of the hypnotic effect of exponential and sigmoid curves upon those who have never used them in serious scholarly work. The lily pond which doubles its leaf-area every day and is half-full on the twenty-ninth day will, so the introduction to this book says, be full on the thirtieth day. Had the author taken the trouble to read the brilliant analysis of population growth published by Alfred Lotka over half a century ago in *Elements of Physical Biology*, he might have hesitated before starting his argument with such a misleading example. The dilemma facing mankind is not what to do about exponential growth; it is how to devise political systems which can be used to manage the second-order consequences which follow the point of inflection of a sigmoid curve of growth.

Forecasts of population growth, oil reserves, capacity of the land to produce food, resources of minerals: all these vary by whole orders of magnitude. Disputes about the forecasts miss the point: that all these parameters already are, or sooner or later will be, above the point of inflection of a sigmoid curve; and the general characteristic of this part of the curve is that feedback, which was positive while the curve was convex to the time-axis, now becomes negative.

Discontinuities invariably occur: nations like China successfully limit the birth rate; nuclear power may replace oil for some purposes; plant breeders may increase yield per hectare, aluminium may replace copper. Some of the discontinuities (for example, the substitution of steam-power for water- and wind-power) have profound social consequences, which have been well documented. But, discontinuities apart, the trend is indisputable; exponentials become sigmoid and the seminal social problem is not how to delay the point of inflection by technological innovation, nor is it how to bring forward the point of inflection by rationing; it is how to manage society when many

measurable variables lie on the upper reaches of sigmoid curves.

This is the worthy theme in Lester Brown's book. In the first nine chapters he covers familiar, not to say overcrowded, ground: the evidence for over-fishing, over-grazing, deforestation; the inevitable rise in population, the geopolitics of energy production, the economic stresses which followed a sixfold increase in oil prices imposed by OPEC and (though western countries are more reticent about this) a two-and-a-half-fold increase in wheat prices imposed by the grain-producing nations and a threefold increase in the price of newsprint; and the growing gap between affluence and poverty.

His sources of information for the material in these chapters are practically all from journalistic and sometimes emotive accounts in the press or in popular books. His exposition of these issues is no worse, and no better, than that in a dozen other books covering similar ground. So it is to the last three chapters, which are about how society is to come to terms with Nature, that I turned with some anticipation. For Lester Brown, unlike many middle-class élitists keen on conservation, has really encountered the world-dilemma at close quarters, as an agricultural officer, as a dweller in Indian villages, and with the Overseas Development Council. This experience (I hoped) would dissuade him from advocating the utopian remedies which prompt decision-makers to drop such books into the waste paper basket.

That Lester Brown's three chapters on accommodation to the new phase of world economy do not provide encouraging solutions is not his fault. No one has come up with even the rudiments of a solution. But Lester Brown does put the emphasis where it belongs, namely on the need to find solutions for social and ethical problems rather than material problems. The great disillusion is not directed against the technologists; it is directed against the economists; and he quotes a telling remark made by Pierre Trudeau: "Inflation has not found its Keynes. I personally think the Keynes of inflation will not be an economist . . ." but will instead "be a political, philosophical or moral leader inspiring people to do without the excess consumption so

prominent in the developed countries". The difficulty is that this recipe may be valid for the inhabitants of Dorking and Wimbledon (well heeled suburbs of London) but not for the swarms of people who squat on the streets of Calcutta. Up to a point there is a close correlation between growth in GNP and the overall improvement in quality of life; it is in affluent societies that the correlation breaks down. So—and this is the conclusion that hurts—the initiative lies in Dorking and Wimbledon and not in Calcutta. And the choice before Dorking and Wimbledon is voluntary adjustment to austerities or submission to bureaucratic regulation.

Some writers—Heilbroner, for example, and Ophuls—are pessimistic about the outcome of this choice. They see (as Heilbroner puts it) the latitude for voluntary choice diminishing "under the slowly closing vise of environmental constraint". Lester Brown is more optimistic, though I confess he does not support his optimism with encouraging arguments. All the same, he is right to be optimistic. The ultimate treason to mankind is to lose confidence in humanity. □

Lord Ashby is a Fellow of Clare College, Cambridge and Chancellor of the Queen's University, Belfast, Northern Ireland.

Photoemission from surfaces

Photoemission and the Electronic Properties of Surfaces. Edited by B. Feuerbacher, B. Fitton and R. F. Willis. Pp 540. (Wiley: Chichester and New York, 1978) £19.50.

THE study of photoemission from solids has grown enormously in the past decade. Although the photoelectric effect has been known for many years and provided a key result for the development of quantum theory, its application to the study of electronic structure of solids is much more recent and the appreciation of its essential surface sensitivity has encouraged its inclusion in the growing armoury of techniques of surface science. Indeed, in the case of ultraviolet photoelectron

spectroscopy in particular, the degree and nature of its surface sensitivity is still an issue of considerable interest. The extent of this development is mirrored by the size of this book, a collection of 17 separate articles on the theory and experimental results of the technique, together with two articles on the intimately related problem of the electronic structure of clean surfaces and adsorbates on surfaces.

The editors have collected together a formidable team of authors for this work; very few of the 'big names' in the subject are missing and the resulting articles are authoritative and thorough. Of course, in any multi-author book, particularly with authors active in an expanding and developing research field, the treatment of the subject is not always even and overlaps do exist, particularly in the introduction of the basic ideas behind several articles. Frequently, however, this overlap is beneficial; the reader is presented with contrasting views of the same material and can emerge with a more balanced appreciation as a result.

Biology of RNAs

The Ribonucleic Acids. (Second edition.) Edited by P. R. Stewart and D. S. Letham. Pp. 374. (Springer: New York, Heidelberg and Berlin, 1978.) DM47.40; \$23.70.

As an antidote to the new-style undergraduate textbooks, awash with coloured diagrams and divided into easily digested segments, *The Ribonucleic Acids* is recommended to students. Here the content is solid, the illustrations mainly restricted to structural formulae in sombre black and white.

This book is intended for students who already have basic training in biochemistry, and, although dealing with a specialist subject, does not aim to be either fully comprehensive or overly detailed. The first chapter is, typically, an historical introduction by the editors and is followed by chapters dealing with different species of RNA—nuclear, transfer, messenger, and so on—and their transcription and translation. The final chapter is a collection of recipes for the preparation and fractionation of RNA, curious in a textbook designed for students but undoubtedly of value to research workers.

Although the chapters have been written by different authors, some attempt has been made to make the style and structure uniform. Reading of the interaction between the 3' end

An intrinsic problem of any book in a very active research field is one of timing; has the subject developed sufficiently to warrant a book or will it be rapidly dated by new developments? In this case the timing seems to be a good compromise. Certainly new developments are occurring, and will continue to occur, which may change the detailed interpretation of specific problems. Also, the construction of many new synchrotron radiation sources around the world is bound to cause a shift in emphasis to the increased use of photon energy and polarisation-dependent effects as a means of studying surfaces. On the other hand, the stress in many articles in this volume is on basic physical principles and as such the book is likely to prove valuable for several years to those involved in, or wishing to learn more about, photoemission from surfaces and their electronic structure.

D. P. Woodruff

D. P. Woodruff is Lecturer in Physics, University of Warwick, UK.

of 16S ribosomal RNA and the 5' end of mRNA in four different chapters suggests that a certain uniformity in content was also required! The balance between cataloguing the facts and critical appraisal of experimental results varies in different chapters, although perhaps some RNAs—nuclear RNA, for example—elicit a more controversial literature.

Distinguishing the characteristics of prokaryotes and eukaryotes is very much easier for research workers, where it is a case of 'us and them', than it is for students, who have no previous affiliations. The latter group of readers will find this book adds to their problems. Sometimes prokaryotes and eukaryotes are allocated different headings, sometimes they are contrasted in the same sentence. This makes the text easier to read and less repetitious, but will undoubtedly perpetuate the existence of that interesting ribosome, found only in undergraduate essays, having 30S and 50S subunits containing 18S and 28S RNAs.

The references accompanying each chapter are extensive, reviews being listed separately. This information, together with the up-to-date overview of the biology of RNA that the text provides, should make this a useful book for research workers in related fields as well as the students for whom the book was written.

WATER CHLORINATION

Environmental Impact and Health Effects Vol. 1

edited by R.L. Jolley, *Oak Ridge National Laboratory, Tennessee.*

Proceedings of the 1975 Oak Ridge Conference.

Presents the current state of knowledge concerning aqueous chlorination with particular emphasis on chlorinated organic compounds and associated biomedical and environmental effects. It establishes a better understanding of both practical and theoretical aspects of water chlorination and sets the stage for solving some of its associated problems.

LKB Multiphor.

For both analytical and preparative electrofocusing.

Multiphor is the central unit in LKB's system for analytical electrofocusing in thin-layer polyacrylamide gel and preparative electrofocusing in flat-bed granulated gel.

The unique Multiphor design enables you to run up to 48 samples simultaneously under identical conditions.

Electrofocusing is performed rapidly by applying a high constant power, possible because of the high efficiency of the glass cooling-plate of Multiphor.

Electrofocusing brings you more information, one-step separation of multi-protein mixtures, and superior resolution.

LKB offers the complete system for electrofocusing: Multiphor, LKB 2103 Power Supply, Ampholine® and Ampholine® PAGplates — your standards in electrofocusing. All supported by LKB Application Notes and *Acta Ampholinæ* Literature Reference List.

For more information write to LKB: the only *complete* source of experience, knowledge and equipment for electrofocusing. LKB Produkter AB, S-161 25 Bromma, Sweden.

THE ACCUMULATION OF A PHYSICAL PROPERTY AS A FUNCTION OF MORTALITY AND MAGNITUDE OF RANK **The Entity Process** Frank Reynolds East

Traditionally, our conceptions of the means by which phenomena—natural and social—occur, reoccur and evolve are based on empirically grounded inquiry presupposing a natural law. By conventional scientific procedure, an effort is made to identify the subject matter, create operating hypotheses, observe the qualities and relations of the item involved, examine its behavior, and ultimately formulate provable mechanistic theory to explain and forecast its existence and nature. Frank Reynolds East, in a work of basic significance, presents a model for accomplishing the same objective which simulates the natural law in purely mathematical terms. His operating principle, called the Entity Process, is the product of statistical invention of an elegant order.

As defined by the author, an entity is a discrete object considered in essential form, independent of its relations with the other members of its component set. It may exist equally in a physical or social context, the primary requirements being that it be uniquely identifiable and subject to rank order. Prediction of its existence and character by means of the Entity Process is predicated on the assumption of what may be called in simplified terms a principle of statistical self-renewal. This principle is applicable to potentially all fields of human concern. For his illustrations the author draws from diverse fields as physics and economics, addressing his theory to a philosophically oriented audience encompassing both the physical and social sciences.

newly on the market

Microtitration plate shakers. Flow. Fixed and variable speed Titertek microtitration plate shakers are now available from Flow Laboratories. Both models use an orbital mode of vibration which has been shown to give even mixing in all plate wells in the minimum time consistent with cell stability and lack of splashing. They have been laboratory tested to prove their ability to resuspend RBCs which have been allowed to sediment overnight. The advantages offered over the manual methods of resuspending are uniformity of results and time/labour-saving.

Circle No. 39 on Reader Enquiry Card.

The Flow Titertek

Nitrate electrode. Electronic Instruments. A nitrate electrode has been added to the range of ion-selective electrodes of Electronic Instruments. Model 8006-2 is of the capsule design ensuring easy assembly and minimal maintenance. The new ion exchanger used gives improved selectivity for NO_3^- in the presence of Cl^- , an important breakthrough in nitrate determinations in sewage and industrial effluents.

Circle No. 40 on Reader Enquiry Card.

Electrophoresis power supplies. Buchler. Buchler Instruments has introduced two new DC power supplies designed for immuno-, paper and thin layer electrophoresis techniques. Each unit features easy to read, oversized meters and a single control for varying the output. One unit has ranges of 0–350 VDC, 0–100 mA and the other unit provides 0–1,000 VDC, 0–200 mA. Both of these units have dual output jacks so that more than one chamber may be operated at the same time.

Circle No. 41 on Reader Enquiry Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Form.

Disposable transfer pipette. Variable Volumetrics. Variable Volumetrics introduce a disposable transfer pipette with ultra lean tube. This polyethylene transfer pipette has a tube so narrow that it will fit into almost any size test tube. It is a one-piece pipette complete with its own bulb, and will eliminate the danger of broken glass, operator contamination from having to change rubber bulbs and cross contamination of samples with contaminated pipettes or rubber bulbs. The pipette delivers 21–24 drops per ml, and has a maximum capacity of 3 ml.

Circle No. 42 on Reader Enquiry Card.

Screening test for blood lead. MSE. An instrument is now available with which a blood sample can be checked in about 10 s to give an indication of the presence of lead in the body. The instrument, the ESA model 4000, uses fluorimetry to measure the amount of zinc protoporphyrin in a drop of blood (about 30 μl). Using the instrument, hundreds of blood samples can be checked in a day. The model 4000 is portable, and extremely easy to operate. The presence of lead in the environment during the analysis cannot affect the result.

Circle No. 43 on Reader Enquiry Card.

UV-monitors and recorders. Pharmacia. Pharmacia presents its new range of UV-monitors and recorders for detecting proteins, polypeptides and nucleic acids in liquid chromatography. The dual path Monitor UV-2 incorporates a flow-cell which allows the simultaneous measurement of the absorbance of a flowing liquid at two different path-lengths. The two measuring systems are completely independent: each can be operated to measure optical density or % transmission at 254 nm or 280 nm. The 1 mm system allows measurements to be made with excellent linearity in eight ranges up to 20 A at the same time as the 20 mm system detects solute concentrations in eight ranges down to a full scale deflection only 0.005 A. The Single Path Monitor UV-1 offers the choice of monitoring absorbance in eight ranges up to 2 absorbance units per cent transmission at 254 nm or 280 nm with a 3 mm or 10 mm path-length flow cell. Also, the one-channel recorder REC-1 and two-channel recorder REC-2 provide a 250 nm recording width, 16 chart speeds and 11 calibrated input ranges with an accuracy of $\pm 0.3\%$ full scale deflection.

Circle No. 44 on Reader Enquiry Card.

Triaxial accelerometer. RIL. The model 507T triaxial accelerometer is a new addition to the BBN range of pre-amplified accelerometers marketed by RIL. It is ideal for applications where low frequencies must be detected or monitored. Technical characteristics include: a flat 10 mV per g response over a frequency range of 0.3–7,000 Hz for each axis; an exceptionally low noise floor of 20 μV broadband, amplitude linearity is $\pm 1\%$ to $+21\text{ g}$ peak; and mounted frequency response is 26 kHz. The preamplifiers in each accelerometer are safeguarded from self-generated transients up to 500 V by a unique protection circuit.

Circle No. 45 on Reader Enquiry Card.

ECG amplifier. British American Optical. A cardio-monitor, designated Model 1134, has been announced. The equipment combines an ECG amplifier and heart rate meter with alarms, in a single compact unit. Patient safety is ensured by the use of isolation transformers, leakage is $< 10\mu\text{A}$ at chassis connectors and insulation withstands 8 KV patient to chassis potential. Remote ECG recording may be initiated manually by means of a push-button. Required power supply is 230 V, 50 Hz.

Circle No. 46 on Reader Enquiry Card.

The British American Optical Model 1134

Protease detection kit. Bio-Rad. Bio-Rad's protease detection kit provides a convenient way to measure the activity of serum proteases, or of other proteases such as trypsin, α -chymotrypsin and pronase. When dissolved, tablets from the kit form an agar gel containing a protein preparation which gives it a turbid appearance. The sample to be assayed is placed in a well and diffuses into the gel forming a clear ring where the protein is digested. Proteolytic activity can then be determined very simply from the ring diameter, using guides provided in the kit.

announcements

Awards

The following awards have been made by the Royal Society: the Copley Medal to **Professor R. B. Woodward** (Harvard University) for his contributions to experimental and theoretical organic chemistry; the Rumford Medal to **Sir George Porter** (Royal Institution) for his work on flash photolysis; the Davy Medal to **Professor A. Eschenmoser** (Swiss Federal Institute of Technology) for his work on synthetic organic chemistry; the Darwin Medal to **Dr G. Pontecorvo** (Imperial Cancer Research Fund) for his advances in genetics utilising lower organisms; the Hughes Medal to **Professor W. Cochran** (University of Edinburgh) for his advances in crystallography and lattice dynamics; the Leverhulme Medal to **Sir Frederick Warner** (Cremer and Warner) for his contributions to the developments of chemical and allied processes on the industrial scale; The Royal Society Eso Award to **A. G. Frame, J. M. Lalthwalte, A. D. Evans, Dr J. F. W. Bishop and Dr T. N. Marham** for their contributions to the development of the prototype fast reactor at Dounreay; the Royal Society Mullard award to **Dr J. W. Black** for his work on the development and discovery of two new types of drugs.

The 1978 ICE Diagnostics Techniques prize winners are **L. M. Callow and K. Hladky** of UMIST for their work on an electrochemical impedance corrosion monitor. The prize of £1,000 is to be awarded annually for five years and is to be administered by the Institution of Chemical Engineers. Entries for the 1979 award are now invited. ICE, 165-171 Railway Terrace, Rugby.

The following have been awarded the Indian National Science Academy's Medals for Young Scientists for the year 1978: **Dr Praveen Chaddah; Dr Renu Khanna Chopra; Dr K. C. Das; Dr A. R. Datta; Dr Vinay V. Deodhar; Shri S. Easwaramoorthy; Dr Chunilal Ghosh; Dr Jitendra Nath Goswami; Dr S. Ramasesha; Dr H. A. Ranganath; Dr Kalidas Sen.**

The Institution of Nuclear Engineers has awarded the first Hinton Medal to **Anthony R. W. Lunt** for his part in the engineering of the Dounreay prototype fast reactor.

The Beilby Medal and Prize for 1978 has been awarded by the RIC, the SCI and the Metals Society to **Dr John Christopher Scully** for his work in corrosion science in particular on stress-corrosion cracking. The award is made to British investigators (normally under the age of 40) for original work in chemical engineering, fuel technology or metallurgy. Applications for the 1979 award should be made to: The Sir George Beilby Memorial Fund, The RIC, 30 Russell Square, London WC1.

The trustees of the Lady Tata Memorial Trust for research in leukaemia have made the following international awards for the academic year 1978-79: from Great Britain—**H. Bayani; A. Karpas and H. Jacobs**; from France—**J. Grosslerner**; from Portugal—**E. Cardoso**; from Spain—**R. de N. Bastos**.

The Harrison Memorial Prize will be awarded to a British subject under the age of 30 years who has conducted the most promising original investigations in chemistry and published the results in a scientific periodical. Applications to the President of the Chemical Society, Burlington House, Piccadilly, London W1, by 31 December 1978.

The sixth of the Henry R. Worthington Technical Award for a prize of 10,000 dollars held under the auspices of the EEC is to be launched on a European-wide basis. It is to be awarded to young researchers from the universities and industry, working in the field of applied mechanics for the movement of fluids and for energy conversion systems. The contest regulations are available from Award Secretariat, Via Pirelli, 19-201234 Milan, Italy.

Meetings

2-3 October, **Workshop on Placenta—the Neglected Experimental Animal**, London (Dr Peter Beaconsfield, SCIP Research Unit, Bedford College, University of London NW1, UK).

2-4 October, **Symposium on Comparative Pathology of Zoo Animals**, Washington (Dr Montali, National Zoological Park, Washington, D.C. 20008).

2-5 October, **Clean Air Ways and Means**, Brighton (National Society for Clean Air, 163 North St, Brighton, Sussex, UK).

3-6 October, **Wind Energy Systems**, Amsterdam (2nd ISWES, BHRA Fluid Engineering, Cranfield, Bedford, UK).

3-6 October, **Postsynthetic Alterations of Information Molecules**, Lunteren (Miss Elly Looy, Institute of Molecular Biology, Padualaan 8, Utrecht, The Netherlands).

3-7 October, **Nuclex 78**, Basle (Congress Service of the Swiss Industries Fair, PO Box CH-4021 Basle, Switzerland).

4-6 October, **National Conference of Standards Laboratories**, Gaithersburg (Brian Belanger, A345 Physics Building, NBS, Washington, D.C. 20234).

4-7 October, **3rd European Symposium on Hormones and Cell Regulation**, Bischenberg (H. J. van der Molen, Dept of Biochemistry II, Medical Faculty, Erasmus University, PO Box 1738, Rotterdam, The Netherlands).

5-6 October, **Carcinogenicity of Foods**, Chicago (Dr John J. Hefferren, ADA Health Foundation Research Institute, 211 East Chicago Ave, Chicago, Illinois 60611).

5-6 October, **Future Trends in Clinical and Laboratory Research in Cancer**, Paris (Dr W. H. Fridman, IRSC, BP No. 8, 94800 Villejuif, France).

5-6 October **International Liquid Chromatography Symposium: Biological/Biomedical Applications**, Boston (Gerald L. Hawk, International Division, Waters Associates, Inc. Milford, Massachusetts 01757).

6-1 October, **Annual Meeting of the Swiss Society of Mineralogy and Petrography**, Brig (Prof. M. Grunfelder, Institut de Cristallographie et Petrographie ETH, 8092 Zurich, Switzerland).

9-12 October, **4th International Congress for the Study of Bauxites, Almina and Aluminium**, Athens (Prof. S. S. Augusthis, National Technical University, Dept of Mineralogy, Petrology and Geography, PO Box 1006, Athens, Greece).

9-13 October, **1st International Congress on Bentonites**, Sassari (Istituto di Mineralogia e Geologia, Facoltà di Agraria, Università de Sassari, Italy).

9-19 October, **Atmospheric Sensing with Lasers**, London (The Institute of Physics, 47 Belgrave Square, London SW1, UK).

10-12 October, **3rd Annual Conference on Materials for Coal Conversion and Utilization**, Gaithersburg (Bernard Levin, B64, Technology Building, NBS, Washington, D.C. 20234).

10 October, **Satellite Doppler Tracking and Geodetic Applications**, London (The Royal Society, 6 Carlton House Terrace, London SW1, UK).

10-13 October, **4th European Electro-optics Conference and Exhibition**, Utrecht (Carole Meads, Sira Institute Ltd, South Hill, Chislehurst, Kent, UK).

10-14 October, **International Symposium on Interaction of Marine Geodesy and Ocean Dynamics**, Miami (Dr George A. Maul, NOAA-AOML, 15 Rickenbacker Causeway, Miami, Florida 33149).

11 October, **Carcinogenic Risks from Food—Real or Imaginary?** London (SCI Food Group, 14 Belgrave Square, London SW1, UK).

12-14 October, **International Symposium on Pituitary Microadenomas**, Milan (Secretariat, Clinica Neurochirurgica dell'Università, Ospedale Policlinico, Pad. Beretta, via F. Sforza 35, 20122 Milan, Italy).

12-18 October, **1st Ibero American Congress of Cell Biology**, Mendoza (Secretariat, Casilla de Correo 56,5500 Mendoza, Argentina).

12-18 October, **4th Latin American Congress of Electron Microscopy**, Mendoza (Secretariat, Casilla de Correo 56,5500, Mendoza, Argentina).

APPOINTMENTS VACANT

AGRICULTURAL RESEARCH COUNCIL

UNIT OF NITROGEN FIXATION

University of Sussex
Brighton BN1 9QJ

MOLECULAR BIOLOGIST

Is required to join an interdisciplinary team working on the physiology, biochemistry and genetics of nitrogen fixation.

The vacancy is for a specialist in molecular biology who will collaborate with genetics and biochemists in a collective study, *in vitro* and *in vivo*, of the products and regulations of the nitrogen fixation genes of *Klebsiella*.

Candidates should have a first or upper second class Honours degree in biochemistry, microbiology or microbial genetics and at least two years' relevant postgraduate research experience.

Appointments as Higher Scientific Officer on the salary scale £4,101 to £5,448 with non-contributory superannuation. Starting salary according to experience.

Applications to the Administrator, Unit of Nitrogen Fixation at the above address. Closing date September 29, 1978. 7099(A)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF GEOLOGICAL SCIENCES

RESEARCH ASSOCIATE IN HYDROGEOLOGY

Applications are invited for the above post to carry out hydrogeological interpretation related to chalk aquifer water resources studies. The study will include hydrochemical appraisal and some borehole and surface geophysics. The work is supported by a research grant from the Anglian Water Authority. Applicants should have a good honours degree in geology and at least an M.Sc. degree in hydrogeology. The post is for three years from November 1, 1978. The successful applicant may be permitted to register for the degree of Ph.D.

Salary in the range £3,384 to £4,882, plus superannuation, maximum starting salary £3,883.

Applications should be sent to Assistant Registrar, Science and Engineering, University of Birmingham, P.O. Box 363, Birmingham B15 2TT (three copies) including curriculum vitae and the names of three referees by Wednesday, September 27, 1978. Please quote Reference NG8. 7135(A)

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (University of London)

Keppel Street, WC1E 7HT

IMMUNOLOGY UNIT

A RESEARCH TECHNICIAN

is required for a period of up to two years to work on the mechanisms of immune complex disease under the direction of Dr M. W. Steward. Experience in biochemical and immunological techniques is essential.

Salary, depending on age, experience, etc., will be in the range £3,615 to £4,284 inclusive.

Applications, consisting of full education and career details and naming two referees, should be sent to Secretary (A1) at the School. 7136(A)

UNIVERSITY OF WARWICK

RESEARCH ASSOCIATE

in the

DEPARTMENT OF CHEMISTRY AND MOLECULAR SCIENCES

Applications are invited for the post of RESEARCH ASSOCIATE with Dr B. E. P. Swoboda to study the detailed mode of action of the anti-tumour agent, cyclophosphamide on normal and cancer cells. Some experience with cell culture, organic syntheses and/or radioisotope techniques would be advantageous and the applicant should have a good degree in Biochemistry or a related subject.

The appointment, which is supported by the Cancer Research Campaign, is initially for one year, with the possibility of extension to three years. Maximum starting salary will be £3,660 per annum on Research Range 1B, plus superannuation. Applications (two copies) giving qualifications and experience and naming two referees should be sent to the Academic Registrar, University of Warwick, Coventry CV4 7AL, as soon as possible, quoting Ref No 4/2A/78. 609(A)

UNIVERSITY OF ABERDEEN

DEPARTMENT OF GENETICS

CYTOGENETICIST

Applications are invited for the above post. The chief requirements include familiarity with modern methods of clinical diagnosis of cytogenetic abnormality, including banding methods and tissue culture. The laboratory is well equipped and there are opportunities for research.

The starting salary will be between £5,000 and £6,000 within Range 1A Research and Analogous scale, according to age and experience.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by September 30, 1978. 7051(A)

CSIRO AUSTRALIA

Postdoctoral Research Fellow

Division of Forest Research Yarralumla, A.C.T.

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7000 employees—2400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: Soil Compaction

General: Modern harvesting machines may cause considerable disturbance to the forest floor, including soil compaction. The Division is concerned about the impact of such disturbance, in native as well as plantation forests, on the soils, hydrology and growth during second rotation cropping.

Duties: Applications are invited from persons interested in initiating research on aspects of soil compaction. The successful candidate will receive cooperation from the Division's sections concerned with soil physics, hydrology and harvesting, but is expected to develop an independent program.

Qualifications: Ph.D. or equivalent qualifications in soil physics or soil mechanics and demonstrable research ability. A broad understanding of forest operations and catchment hydrology is desirable.

Salary: Research Scientist or Senior Research Scientist: \$A14,829 — \$A21,643 p.a.

Tenure: Fixed term of 5 years, with Australian Government Superannuation benefits.

Applications IN DUPLICATE, stating FULL personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 1069/119 should reach: The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, LONDON WC2R 3EH by 15th October 1978.

Applications in U.S.A. and Canada should be sent to: The Counsellor (Scientific), Embassy of Australia, 1801 Massachusetts Avenue, N.W., WASHINGTON, D.C., 20036, U.S.A.

7090(A)

Laser Scientists

RUTHERFORD LABORATORY

South Oxon.

The Rutherford Laboratory is the Science Research Council's principal establishment for advanced work on the frontiers of physics, and one of Europe's leading centres for laser research.

The Laser Division now has vacancies for two Scientific Officers in experimental physics.

Plasma Physics

The successful applicant will join a small experimental team providing facilities for and collaborating with University users of the SRC Laser Facility. The experiments are concerned with the study of laser-plasma interactions and laser driven implosion and compression. The work involves the alignment of small targets in the focus of the laser beam, operation of plasma measurement devices, analysis of experimental data and development of new measurement systems.

You should have a University degree in a relevant subject. Experience in optics or pulse electronics would be advantageous.

Target Fabrication and Development

The selected candidate will become part of a small group preparing microscopic but complex targets for irradiation by the high power laser beams.

You will carry out development work on new target manufacture measurement and coating techniques and be responsible for the supply of targets for the experimental programme. The work involves the use of vacuum and high pressure gas handling equipment, optical microscopes and interferometers, X-radiography equipment and a scanning electron microscope.

You should have an HNC in Applied Physics or equivalent qualification in a relevant subject. Experience in thin film coating techniques or use of any of the above equipment would be desirable.

Scientific Officer salaries are in the £3,037 – £4,724 (including supplements) with prospects of promotion to higher grades and salary scales.

Working conditions are excellent and benefits include generous holidays, sick leave allowance and contributory superannuation scheme.

Write or telephone for an application form to:
Ruth Jeans of the Personnel Group.
Please quote reference VN735 and state
which post you are interested in.
Closing date for applications 30th Sept. 1978

7132(A)

RESEARCH ASSISTANT

Graduate required to join a team of scientists investigating basic aspects of cardiac biochemistry and physiology. A training in physiology or biochemistry and experience in spectrophotometry, tissue metabolite analysis or organ perfusion would be advantageous. The research unit is located in the new Rayne Institute and appointments will be made through St Thomas's Hospital Medical School. Applications together with a curriculum vitae should be sent to Dr D. J. Hearse, The Rayne Institute, St Thomas's Hospital, London SE1.

THE UNIVERSITY OF PAPUA NEW GUINEA (PORT MORESBY)

Applications are invited for the post
of

TUTOR/ ASSISTANT LECTURER

in the
DEPARTMENT OF GEOGRAPHY

Preference will be given to candidates with teaching and research interests in Agricultural Geography and/or Human Ecology. The appointee will be required to make a major contribution to the Social Studies course in the Arts Faculty Foundation Year, and the Man and His Environment course in the Science Faculty. In addition he/she will have teaching duties in some of the more Advanced Geography courses. There are ample opportunities for research in Papua New Guinea and if appropriate the appointee will be encouraged to enrol for a higher degree. Appointment will be for a period of two years in the first instance. Salary scale: K7,323 to K8,382 p.a. (£1 sterling=K1.33). In addition, an allowance of K1,300 p.a. if single is payable. An extra K1,000 Marriage Allowance and K156 per child Child Allowance may also be payable. There is also provision of housing and annual leave fares. Detailed applications (2 copies) with curriculum vitae and naming three referees plus small photograph to be sent direct to Secretary, Box 4820, University PO, Papua New Guinea by October 6, 1978. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

7093(A)

INSTITUTE OF PSYCHIATRY TECHNICIAN

required in the Department of Neuropathology to assist with electronic data processing connected with biochemical research. An applicant keen to learn need have only some of the relevant biological or mathematical background. Training will be given in data processing and in electronic and biochemical techniques, according to the applicant's background and previous experience. Unusual opportunity to gain broader experience of modern microprocessor-based techniques.

This position is grant supported for three years with possibility of extensions. Whitley Council conditions of service. Salary in the range £3,261 to £4,680 per annum plus London Weighting £354 per annum.

For application form please write to the Assistant Secretary, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF or telephone 703 5411, Ext. 214, quoting reference OEP/N.

7092(A)

LAKEHEAD UNIVERSITY POSTDOCTORAL FELLOW SURFACE CHEMISTRY

Position available in small group active in surface chemistry and heterogeneous catalysis. Stipend and benefits up to maximum allowable by N.R.C. regulations.

Please forward applications with names of two referees to:

Dr R. A. Ross
Professor of Chemistry
Lakehead University
Thunder Bay
Ontario
Canada P7B 5E1

7122(A)

N.M.R. SPECTROMETRY ASSISTANT

King's College, London

Applications are invited for the
above

TECHNICIAN GRADE 5

post to assist in the operation/maintenance of a Bruker HFX 90 F¹ n.m.r. spectrometer. Previous experience of spectroscopic or of other advanced electronic instrumentation desirable. Initial instruction will be given if required. Salary on scale £3,651 p.a. rising to £4,185 p.a. (inclusive) for a 37½ hour week Monday to Friday. 4 weeks' annual holiday. Contributory pension scheme. Applications in writing with full details to: The Head Clerk, Ref. 204008, King's College London, Strand, WC2R 2LS

7071(A)

UNIVERSITY OF OXFORD DEPARTMENT OF AGRICULTURAL SCIENCE RESEARCH ASSISTANT

with a good honours degree, a driving licence and an interest in fungal taxonomy and pathology to assist on a N.E.R.C. funded project to monitor disease in plant communities over three years.

Starting salary £3,189 on Grade 1B.

Applications with the names of two referees by September 30 to the Administrator, Department of Agricultural Science, Parks Road, Oxford OX1 3PF, from whom further particulars can be obtained.

7123(A)

MAX-PLANCK-INSTITUTE Tübingen, Germany POSTDOCTORAL RESEARCH POSITION IN TUMOUR VIROLOGY

open, beginning January 1979, or earlier. Applicants with Ph.D. or M.D. degrees should have some experience in immunology and/or (tumour) virology to join a research group working on cell surface and nuclear alterations of virus transformed cells.

Salary around 30,000 German Mark per annum.

Some knowledge of German is desirable, but not absolutely necessary. Applications should be sent to:

Dr R. Kurth
Friedrich-Miescher-Laboratorium
Max-Planck-Institutes
Spemannstr. 37-39
74 Tübingen, W. Germany

7124(A)

MOREDUN RESEARCH INSTITUTE BIOCHEMISTRY DEPARTMENT S.O./H.S.O.

A SCIENTIST is required to join a small team. The appointee will be responsible for initiating and conducting research on the biochemical consequences of parasitism and certain other diseases in ruminants. Applicants should have a first or upper second class Hons. Degree in Biochemistry or Agricultural Chemistry. At least 2 years postgraduate experience is required for appointment as H.S.O.

Salary scale: S.O. £2,839 to £4,415. H.S.O. £4,101 to £5,448. Non-contributory superannuation scheme. Starting salary will be dependent upon qualifications and experience.

Applications giving the names and addresses of 2 referees should be sent to the Secretary, Animal Diseases Research Association, Moredun Institute, 408 Gilmerton Road, Edinburgh EH17 7JH.

CHANGE OF ADDRESS

The Advertisement offices for NATURE have moved to
3 DYERS BUILDINGS, LONDON, EC1N 2NR
TELEPHONE : 01 831-6901

UNIVERSITY
OF MANCHESTER
DEPARTMENT OF MEDICAL
BIOCHEMISTRY
POSTDOCTORAL
RESEARCH ASSISTANT
IN BIOCHEMISTRY

A postdoctoral research assistant sponsored by the Medical Research Council is required from October 1978, earlier if preferred. The work, under the supervision of Jacqueline B. Weiss, involves the characterisation and spatial recognition of new collagen alpha chains and the person appointed will be part of a multi disciplinary team of whom one is an electron microscopist. Experience in collagen biology or biochemistry would be a very welcome but experience in mineral protein chemistry would also be acceptable. The appointment is for three years only. The salary scale is in the range £4,365 to £4,834 p.a. Applications, including curriculum vitae, to Jacqueline B. Weiss, Senior Lecturer, Department of Medical Biochemistry, Medical School, Stopford Building, Oxford Road, Manchester M13 9PT. 7075(A)

THAMES POLYTECHNIC
SCHOOL OF MATERIALS
SCIENCE AND PHYSICS
RESEARCH ASSISTANTS

A research assistant is required in the Division of Physics to investigate the properties of semiconductor layers grown by liquid phase epitaxy. A second research assistant is required in the Division of Materials Science to investigate, either the properties and preparation of (a) new organic luminescent materials, or (b) new photo-voltaic materials.

Candidates should have good honours degrees in physics, materials science or chemistry. Previous experience in the above areas is not required and successful candidates will register for higher degrees of the C.N.A.A.

Salary scale, £3,015 to £3,189 inclusive.

Further particulars and form of application may be obtained from the Staffing Officer, Thames Polytechnic, Wellington Street, London, SE18 6PF, to whom completed applications should be returned by September 26, 1978. 7080(A)

ROTHAMSTED
EXPERIMENTAL STATION
Harpenden, Herts. AL5 2JQ
STATISTICIAN

to be responsible for a continuing agricultural survey. The work involves liaison with collaborating organisations, organisation of data coding, analysis and reporting of results. There will also be opportunities for research on problems of interpreting observational data.

Qualifications: Degree, HNC or equivalent qualification in Statistics with at least five years' relevant post-qualifying experience. Previous experience with responsibility for staff would be an advantage.

Appointment in grade of Higher Scientific Officer (£4,101 to £5,448 p.a.). Starting salary according to experience. Non-contributory superannuation.

Apply in writing to the Secretary, giving names and addresses of two referees and quoting Ref 369 by October 5, 1978. Further details on request. 7070(A)

UNIVERSITY OF
EDINBURGH
DEPARTMENT OF BOTANY
POSTDOCTORAL
RESEARCH FELLOW

A Postdoctoral Research Fellow is required for two years for an experimental investigation of "The Transition to Flowering in *Silene*". This work is supported by the Agricultural Research Council and will involve the experimental manipulation and measurement of the growth of plants in controlled environments, measurement of cell cycle parameters by microdensitometry and autoradiography, scanning electron microscopy, and histology.

Salary on range 1A, £3,660 to £6,178 per annum, according to age and experience.

Applications, with a curriculum vitae and the names and addresses of two referees, should be sent as soon as possible to Dr R. F. Lyndon, Department of Botany, University of Edinburgh, Mayfield Road, Edinburgh EH9 3JH. Please quote Reference 5048. 7119(A)

ST GEORGE'S HOSPITAL
MEDICAL SCHOOL
(University of London)
RESEARCH ASSISTANT

Graduate or postdoctoral person required in the Physiology Department to participate in a 2 to 3 years Arthritis and Rheumatism Council research project into the control of fluid movement between the synovial cavity and micro-circulation of mammalian joints. Applicants should hold an upper-second or first-class degree in animal physiology and have a special interest in mammalian cardiovascular/body fluid physiology. Excellent research facilities are available in this modern, recently established Department and the opportunity exists for a graduate to undertake a higher degree during the tenure of the post. Salary scale £3,212 to £3,447 p.a. plus £450 London allowance. Applications, with the names of two referees, to the Establishment Officer, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE. 7104(A)

THE
UNIVERSITY OF LEEDS
DEPARTMENT OF
PLANT SCIENCES

Applications are invited for the temporary fixed-term post of post-doctoral RESEARCH FELLOW to work with Dr L. D. Incoll on a project concerned with work on when and how cytokinins open graminaceous stomata.

Ideally applicants should have been trained at the postgraduate level in research on phytohormones and should have research experience in that field. Appointment is for one year in the first instance, renewable for up to a total of three years. Initial salary will be in the range £3,883 to £4,382 per annum (within the 1A range of the scale for Research and Analogous staff.) (Under review).

Applications, giving curriculum vitae and the names of two referees, should be sent by October 5, 1978 to Dr L. D. Incoll, Department of Plant Sciences (Bailey Wing), The University of Leeds, Leeds LS2 9JT, from whom further details may be obtained. 7073(A)

Coal Survey Specialists

£7000-£8825 based Yorkshire

The National Coal Board have opportunities for 2 Coal Quality Scientists to work as part of a National Exploration team based in Yorkshire which has the task of establishing the long term coal reserves of the nation.

The main work will involve the synthesis of data from boreholes as exploration proceeds; the identification of those quality parameters to which the profitability of any coal mining venture would be most sensitive; and the evaluation of each prospect within both its Regional and National exploration setting. The successful applicants will also participate in appraising the coal quality and utilisation aspects of the Board's major capital investments programme for the development of new capacity.

Applicants should hold an honours degree in either chemistry, geochemistry, fuel technology or a related subject. Experience in one or more of the following fields would be an advantage: fuel technology, coal analysis and utilisation, coal preparation, geological data analysis.

A period of supervision and training will be given where appropriate.

These are permanent positions within Headquarters Geological Branch with an inclusive salary range of £7000-£8825. Attractive conditions of employment.

Please apply with full details to:

NCB

Headquarters Staff Manager,
National Coal Board,
Coal House, Doncaster, South Yorkshire.

CHANGE OF ADDRESS

The Advertisement offices for NATURE have moved to
3 DYERS BUILDINGS, LONDON, EC1N 2NR
TELEPHONE : 01 831-6901

**THE NEW SOUTH WALES
INSTITUTE OF TECHNOLOGY**
Sydney, Australia

SCHOOL OF LIFE SCIENCES
**Associate Head of School and Head,
Department of Cellular Pathology
and Microbiology**

The New South Wales Institute of Technology is a corporate tertiary institution, established to provide a wide range of professional courses for those entering or already employed in industry, government, and technological fields.

The School occupies a six-storey building at Gore Hill adjacent to the Royal North Shore Hospital. There are well equipped laboratories for teaching and research in Pathology, Microbiology, Biochemistry, Environmental Biology, Physical Biology and General Biology. The School also jointly operates the Gore Hill Research Laboratories with the Royal North Shore Hospital.

The appointee will be responsible to the Head of School for the teaching and development of undergraduate and postgraduate programmes in cellular pathology and microbiology. This will include the continuing development of courses in immunology, haematology, diagnostic cytology and clinical microbiology. The appointee will also be required to study current trends in the fields mentioned, and to make recommendations on new undergraduate and postgraduate courses.

It is anticipated that the appointee will be qualified in medicine or an area of medical science, possess appropriate postgraduate qualifications and have substantial professional experience. Depending on their interests and experience they may be offered an association with the Royal North Shore Hospital.

Salary will be in the range of \$A29,612 — \$A31,789. With consent of Council, academic staff are permitted to undertake limited consulting work.

The position offers tenure, superannuation, long service leave, and a Housing Loan Scheme. Fares and a contribution toward removal and initial accommodation expenses are provided for overseas appointees.

Dr R. L. Werner, President of The Institute, will be in London from the 11th to the 26th of September, and will be available to provide further information on this position through the Agent General's office on 01-839 6651.

Applications close on October 31, 1978. Applicants should arrange for three confidential referees' reports to arrive by the same date. Applications should include: address; phone number; personal particulars; documentary evidence of qualifications; work and teaching experience; affiliations; publications; research work undertaken and the names and addresses of the referees contacted. Applications and referees' reports are to be sent to:

The Agent-General for N.S.W.
N.S.W. Government Offices
66 STRAND

**THE POLYTECHNIC
OF NORTH LONDON**
PHYSICS DEPARTMENT

Applications are invited from graduates for a

RESEARCH ASSISTANTSHIP
in experimental physics. The fields of research are:

Development of microwave excited spectroscopic light sources;
Investigation of the properties of thin magnetic films;

Development of low background counters for studying cosmic and environmental radiation.

Salary scale: £3,015 to £3,189 (including London Allowance). Duties include six hours of teaching per week. A suitably qualified candidate may be allowed to register for a research degree.

Applications should be made as soon as possible to the Head of the Department of Physics, Polytechnic of North London, Holloway, London N7 8DB, from whom further details may also be obtained.

7094(A)

NEUROSCIENCES FACULTY

Faculty positions available in the Neurosciences Program, Maryland Psychiatric Research Center, affiliated with the University of Maryland School of Medicine. One position is open to a

SCIENTIST

with rigorous postgraduate training in neuroendocrinology, basic expertise in hormone assay procedures and the capability to study functional aspects of hormones/polypeptides in a multi-disciplinary clinical research centre. The second position is for a SCIENTIST with rigorous postgraduate training in a neurobiology specialty with preference given to strength in biochemistry and/or genetics plus experience in cell or organ culture techniques.

Submit curriculum vitae, summary of research interest and two letters of reference by November 15, 1978, to: Neurosciences Search Committee, Maryland Psychiatric Research Center, Box 3235, Baltimore, Md. 21228. An Equal Opportunity Employer.

7060(A)

THE UNIVERSITY OF CALGARY

**MORPHOLOGICAL
SCIENCE**

The Faculty of Medicine, The University of Calgary, Calgary, Alberta, invites applications for the position of Professor and Head, Division of Morphological Science.

Candidates should have an established record of achievement as a scholar, an active research programme, and a strong background related to teaching anatomy in a medical school using the systems method.

Applications, including an up-to-date curriculum vitae should be forwarded to:

Dr. L. E. McLeod, Dean
Faculty of Medicine
The University of Calgary
Calgary, Alberta

**PUBLIC HEALTH
LABORATORY
SERVICE BOARD
SCIENTIFIC OR SENIOR
SCIENTIFIC OFFICER
AT THE MYCOLOGICAL
REFERENCE LABORATORY,
LONDON SCHOOL OF
HYGIENE AND
TROPICAL MEDICINE,
Kippell Street (Gower Street),
London WC1E 7HT**

Applications are invited from graduates who have a primary training in medical mycology or microbiology and experience with the handling and identification of pathogenic micro-organisms. The successful candidate will be required to assist with the handling and identification of pathogenic fungi with serodiagnostic and antifungal tests, and to develop independent research interests in the field of medical mycology. The level of appointment will depend on qualifications and experience but will be on the scale £2,991 to £4,899 (Scientific Officer) or £5,451 to £6,837 (Senior Scientific Officer), plus London Weighting allowance of £364. Terms and conditions of service similar to National Health Service. The laboratory may be visited by arrangement with the Director, Professor D. W. R. Mackenzie (telephone 01-636 8686 ext 361) who can provide a brief job description of the post. Applications to Professor Mackenzie at the London School of Hygiene and Tropical Medicine, stating date of birth, qualifications, experience including published work, and naming 3 referees. Closing date September 30, 1978. 7087(A)

TECHNICIAN (Grade 4) required to work in Fermentation Pilot Plant Laboratory. Duties include microbiological/analytical work and operation of laboratory fermenters. The successful applicant will be required to operate a limited day shift system (09.00 to 17.00 hrs: 6 x duty days, 3 x rest days). Salary in the range £3,674 to £4,121 p.a. inclusive of London Weighting and shift inconvenience allowance. Enquiries in writing to: Departmental Superintendent, Biochemistry Department, Imperial College, South Kensington, London SW7 2AZ. 7126(A)

**Southampton
THE
UNIVERSITY**

CHAIR OF GEOLOGY

Applications are invited for a further Chair of Geology which is to be established during the academic year 1978/79.

Salary within the professional range.

Applicants may have teaching and research interests in any field of study appropriate to a University Department of Geology.

Further particulars may be obtained from the Secretary and Registrar, The University, Southampton SO9 5NH, and applications (10 copies from applicants in the United Kingdom) must be submitted before November 5, 1978. 7130(A)

BIOCHEMICAL GENETICIST

Research Assistant wanted to work on inherited variations of proteins in mice. Starting salary £3,834 p.a. (scale 1b). Applications, with names of two referees, to be sent as soon as possible and not later than September 29, to Professor R. J. Perry, Royal Free Hospital School of Medicine, 8 Hunter Street, London WC1N 1BP. 7100(A)

**UNIVERSITY OF OXFORD
DYSON PERRINS LABORATORY
(ORGANIC CHEMISTRY)**

Applications are invited for a post-doctoral research assistant supported by the Medical Research Council to work in the mechanism of action of cyclic macrolide antibiotics. Experience in nuclear magnetic resonance is desirable but not essential, and this will be the main technique used. The appointment will be for a period of up to two years in Research Support Grade 1A at an appropriate point of the salary scale up to £4,365 p.a. plus U.S.S., the preferred starting date is January 1, 1979. Applicants should write as soon as possible giving full personal details and naming two referees to Dr J. M. Brown, Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY. 7102(A)

**UNIVERSITY OF LEICESTER
DEPARTMENT OF GENETICS**

TWO Post-doctoral positions are available to work on the mechanism of action of penicillin and the use of the antibiotic to study the processes of bacterial cell division and shape determination.

ONE position is M.R.C. funded for three years and the other is funded by Iocchst Pharmaceuticals for two years in the first instance. Both positions are on the salary scale 1A (£3,660 by £235, under review) and are available from October 1 or as soon as possible hereafter.

Applications including a curriculum vitae and the names of two referees should be sent to Dr Brian G. Spratt, Department of Genetics, University of Leicester, Leicester LE1 7RH as soon as possible. 7101(A)

**Geology and Geophysics
UNIVERSITY OF
CALIFORNIA, BERKELEY**

An Assistant Professorship in Geology is an anticipated vacancy, pending budgetary approval, to be filled July 1, 1979 in the Department of Geology and Geophysics. Candidates must have an expertise which will contribute to an integrated programme of field and laboratory research and teaching. Research emphasis may be in the areas of metamorphic petrology, structure-stratigraphy, or tectonics. The position will require teaching and research supervision in the field. The Ph.D. degree is required.

Applications should be submitted by December 15, 1978 to:

T. V. McEvilly, Chairman
Geology and Geophysics
University of California
Berkeley, Ca 94720

and should include the names of three academic referees.

The University of California is an Affirmative Action employer. 7105(A)

**AGRICULTURAL
RESEARCH COUNCIL
INSTITUTE OF
ANIMAL PHYSIOLOGY
Babraham, Cambridge CB2 4AT
VASCULAR BIOLOGY**

Applications are invited for a post in the Department of Cell Biology, tenable for three years, on a project financed by the M.R.C. This project, under the supervision of Dr J. L. Gordon, will involve studies on the control of vascular tone and permeability, using cultured endothelial and smooth muscle cells, and isolated vascular preparations. Experience with such techniques, with biochemical correlates of contractility, or with transport, metabolism or secretion of vasoactive agents (e.g. prostaglandins and amines) would be advantageous. Candidates should possess a 1st or upper 2nd class Honours degree in biochemistry or related science, together with at least 2 years' relevant post-qualifying experience. Preference will be given to candidates with relevant postdoctoral experience. Appointment will be to the H.S.O. grade (£4,101 to £5,448) or to the S.S.O. grade (£5,154 to £6,898) depending on experience. Applications, including C.V. and the names of two referees, should be sent to the Secretary By September 30, 1978. Quote Ref J.L.G. 7106(A)

**AUSTRALIAN NATIONAL
UNIVERSITY**

Applications are invited for appointment to the following:

**Research School of
Biological Sciences
DEPARTMENT OF
POPULATION BIOLOGY
RESEARCH FELLOW**

The Department has a small group interested in genome structure and evolution in eucaryotes. Current interests encompass both genetic as well as molecular studies on *Drosophila* and rodent genomes, with emphasis on highly repeated DNA. The applicant should have postdoctoral research experience and be interested in developing a programme on some aspect of genome structure. The applicant should preferably be familiar with current molecular techniques, preferably DNA cloning, restriction endonuclease digestion of DNA and electron microscopy.

Appointment of Research Fellow is for three years in the first instance with the possibility of extension to five years.

CLOSING DATE October 15, 1978
SALARY Salary on appointment will be in accordance with qualifications and experience within the range Research Fellow \$A15,179 to \$19,811. Current exchange rates \$A1=\$US1 15 58p.

OTHER CONDITIONS Reasonable appointment expenses are paid. Superannuation benefits are available for applicants who are eligible to contribute. Assistance with housing is provided for an appointee from outside Canberra.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should obtain the further particulars from the Association of Commonwealth Universities (Acpts), 36 Gordon Square, London WC1H 0PF. 7097(A)

**CSIRO
AUSTRALIA
Post Doctoral
Research
Fellow
Division of
Plant Industry
Canberra Act**

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7000 employees—2400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: Molecular Biology

General: The Division, with headquarters in Canberra, ACT, conducts pure and applied research in genetics, plant breeding, genetic resources, biochemistry, physiology, microbiology, plant nutrition, ecology, crop adaptation, soil fertility and plant introduction.

The position is in the Plant Storage Protein Group which is an interdisciplinary unit incorporating biochemists, geneticists, physiologists and plant nutritionists. Work in progress includes studies on the biosynthesis of pea storage proteins and on the characterization of the genetic elements involved. Related activities in the Division include studies on chromosome structure and replication, the genetics of regulatory processes, and a study of the organisation, function and expression of the chloroplast genome.

Duties: To participate in a research program involving molecular studies on gene expression in higher plants. It is anticipated that recombinant DNA procedures will be used, in conjunction with other molecular biology techniques, to analyse in detail the organization and expression of storage protein genes in peas.

Qualifications: Applicants should have a Ph.D. degree in an appropriate field or postgraduate research experience of equivalent standard or duration supported by satisfactory evidence of research ability.

Salary: The appointment will be made within the salary ranges of Research Scientist or Senior Research Scientist: \$A14,829 — \$A21,643 p.a.

Tenure: The position is available for two years.

Applications **IN DUPLICATE**, stating **FULL** personal and professional details, the names and addresses of at least two professional referees, and **QUOTING REFERENCE NUMBER 130/1431** should reach: The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, LONDON WC2H 3EH by 15th October 1978.

Applications in U.S.A. and Canada should be sent to:—The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., WASHINGTON, D.C., 20036, U.S.A.

Microbiologist

G. D. Searle is a leading Pharmaceutical company with its main U.K. site and Research laboratories at High Wycombe in Buckinghamshire.

Within the laboratories we are involved in a growing number of long-term research and development programmes in various fields of medical science.

The position of Microbiologist would ideally suit an experienced man or woman who would join the Research and Development Division to take on responsibility for several branches of microbiological work, primarily the monitoring of sterile production and testing facilities, but also providing microbiological advice for programmes on fermentation development and microbiological research programmes. The person appointed will report to the Biological Quality Control Manager.

Candidates should have several years' experience in this field, probably with a PhD and possibly with specific experience of microbiological aspects of tissue culture based vaccine production. All applicants must have at least a working knowledge of GMP requirements and should enjoy a real challenge - with the potential satisfaction of making significant advances in the world of medicine.

In addition to a competitive salary, conditions of employment include 4 weeks' holiday per year, a contributory pension fund, subsidised private health insurance, sports and social club and staff cafeteria.

Applications are requested, quoting reference M/R16, either in writing, giving career details, or by telephoning for an application form to: G. Jenkins, Personnel Manager, Research & Development, G. D. Searle & Co. Ltd., Lane End Road, High Wycombe, Bucks. (Tel. High Wycombe 21124 ext. 3272).

7129(A)

NATAL MUSEUM Pietermaritzburg, South Africa VACANCY FOR A DIPTERIST

Applications are invited for a vacancy in the Department of Entomology at the Natal Museum. The appointee will be required to take charge of the Department and undertake taxonomic research on Diptera. A person interested in one of the families Tachinidae, Cecidomyiidae, Dolichopodidae or Phoridae, is particularly sought, but applicants with other interests will also be considered. The minimum academic requirement is an Honours degree. Full details of the post and application forms can be obtained from the Director at 237 Loop Street, Pietermaritzburg 3201, South Africa. 7033(A)

MEDICAL RESEARCH COUNCIL TOXICOLOGY UNIT PHARMACOLOGIST/ PHYSIOLOGIST

required as part of a long-term programme to build up expertise for studies of the mechanism of action of toxic substances on specific organs or preparations *in vivo* and *in vitro*. He will have opportunities for interdisciplinary studies with other members of the staff as well as detailed discussions with Professor E. Zaimis of the Department of Pharmacology, Royal Free Hospital Medical School. The post will be a three-year post-doctoral temporary appointment.

Apply in writing by the end of September enclosing a full curriculum vitae to Dr W. N. Aldridge, Toxicology Unit, Medical Research Council Laboratories, Woodmansterne Road, Carshalton, Surrey SM5 4EF. 7048(A)

DIRECTOR DIVISION OF FORENSIC MEDICINE HEALTH COMMISSION OF NEW SOUTH WALES and PROFESSOR or ASSOCIATE PROFESSOR DEPARTMENT OF PATHOLOGY THE UNIVERSITY OF SYDNEY (Joint appointment—Health Commission and University of Sydney)

Salary: \$A35,275 p.a.

Qualifications: Medical practitioners eligible for registration in New South Wales and qualified and experienced in forensic pathology.

Duties: (1) Responsible to the Health Commission for the administration of the Division of Forensic Medicine which performs forensic autopsies on behalf of the Sydney City Coroner and the Coroners of several suburban areas and provides a forensic pathology consultant service to country areas in New South Wales, as well as forensic tests and examinations on behalf of the Police Department; and (2) responsible to the University of Sydney for teaching and research in Forensic Medicine in the Faculty of Medicine.

General: The successful applicant will be offered permanent appointment to the New South Wales Health Commission under the New South Wales Public Service Act (1902). Subject to medical examination, he/she will be eligible for New South Wales State Superannuation.

The appointee will also be given the title of Professor or Associate Professor by the University of Sydney and will have access to research facilities in the Department of Pathology within the University.

Fares and Removal Expenses: Assistance towards fares, removal and initial accommodation expenses for interstate or overseas applicants will be considered.

Enquiries: Dr T. Rennie, Health Commission of New South Wales, 9-13 Young Street, Sydney, NSW 2000, re appointment as Director, Division of Forensic Medicine, under New South Wales Public Service Act; and to the Dean, Faculty of Medicine, University of Sydney, NSW 2006, re appointment as Professor or Associate Professor in the Department of Pathology, University of Sydney.

Applications giving full details of qualifications and experience and names of three referees by **October 3, 1978** to the Registrar, University of Sydney, NSW 2006, Australia. Information also from Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF. 7098(A)

THE UNIVERSITY OF MANCHESTER INSTITUTE OF SCIENCE AND TECHNOLOGY ASSISTANT DIRECTOR OF THE POLLUTION RESEARCH UNIT

Applications are invited from suitably qualified engineers or scientists to lead the U.M.I.S.T. group of the Pollution Research Unit organised jointly with the University of Manchester. The successful candidate should ideally be able to undertake the following:—

- (1) Fundamental or applied research in the pollution field.
- (2) Contributions to the organisation and teaching of an existing successful M.Sc. course.
- (3) Short courses.
- (4) Consultancy and test work for industry.

Industrial experience would be an advantage. Excellence in all the above fields is not essential provided the applicant possesses the paramount ability to motivate and coordinate interdisciplinary activities within U.M.I.S.T. and the University, while cooperating fully with the Director, who is located at the University.

Salary will be within scale £7,074 p.a. to £8,730 p.a. (under review).

Applications and further particulars may be obtained from the Registrar, U.M.I.S.T., P.O. Box 88, Manchester M60 1QD. Quote Reference PR/153/A1. Closing date: October 13, 1978. 7110(A)

LANCASHIRE COLLEGE OF AGRICULTURE SCHOOLS LIAISON OFFICER

Applications are invited for the newly created post of Schools Liaison Officer at the Lancashire College of Agriculture. Salary will be on the Lecturer Grade 2 scale for Farm Institute staff up to a maximum of £7,251 p.a. dependent upon qualifications and experience. Car allowance payable. The person appointed will be concerned with the establishment and development of a school liaison unit and knowledge or experience of relevant school work would be an advantage. Further details and forms of application are available from:—

The Principal Agricultural Officer,
Lancashire College of Agriculture,
Myerscough Hall,
Bilsborrow,
Preston PR3 0RY,
Lancashire.

Telephone: BROCK (0995) 4061.

to whom completed applications should be returned not later than October 9, 1978. 7112(A)

TELEPHONE: 01 831-6901

UNIVERSITY OF RHODESIA
FACULTY OF ENGINEERING
CHAIR OF MECHANICAL
ENGINEERING
LECTURESHIPS
IN ELECTRICAL
AND MECHANICAL
ENGINEERING

Applications are invited from persons with engineering degrees and post-graduation experience for:—

Professor and Head of Department of Mechanical Engineering.

Lecturer or Senior Lecturer in the Department of Electric and Power Engineering (preferably with experience in Electric Power Systems, Electrical Machines, and Electromagnetics), and in the **Department of Mechanical Engineering** (preferably with experience in Thermodynamics, Heat Transfer and Mechanical Design).

Salary Scales (Approx. Stg. equiv.):

Professor
£10,461 by 394 to £12,431

Senior Lecturer
£7,606 by 295 to £8,491 by 313 to £10,056

Lecturer Grade I
£6,899 by 259 to £7,935

Lecturer Grade II
£4,260 by 224 to £5,380 by 259 to £6,675

Subject to University permission limited extra earnings for consultancy may be retained in full. Above this limitation they are shared with the University.

Commencing salary according to qualification and experience. Family passages and allowance for transport if effects; installation loan; travel allowance for Sabbatical and Biennial Professor) or Triennial (Lecturers) visits; superannuation and medical aid schemes. For persons recruited outside Rhodesia, unfurnished accommodation in or near the Campus, and within easy reach of good Junior and Senior schools, is guaranteed for up to three years.

Appointments: These may be on permanent pensionable terms or for a fixed term of 1 or 2 years in the first instance. In the case of 1 and 2 year contracts a non-pensionable salary is payable as above plus a 10% supplement. Unless born in Rhodesia ex-atriates on contract are exempted from Military Service.

Applications: One copy giving personal particulars (including full names, place and date of birth), qualifications, fields of special interest, experience and publications, and giving names and addresses of three referees should be sent by **November 17, 1978** to The Senior Assistant Registrar (Engineering), University of Rhodesia, P.O. Box 417, Mount Pleasant, Salisbury, Rhodesia, from whom further particulars may be obtained. Overseas applicants please send an additional copy to: the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom further particulars may also be obtained. Applicants should state in their applications the earliest date available and also the preferred date.

British subjects considering applying for posts in Rhodesia are urged to consult the Foreign and Commonwealth Office (telephone 233-4143) or their nearest British Consular Office.

A CAREER IN APPLIED PHYSICS?

Opportunity for a Scientific Officer at the Daresbury Laboratory.

Daresbury Laboratory, an establishment of the Science Research Council situated in the north Cheshire countryside, is constructing the world's first high energy (2 GeV) electron storage ring specifically designed to provide a large number of synchrotron radiation beams. This new National Facility is to be commissioned in 1980 and will be used by well over 100 British and foreign experimental teams from many scientific disciplines including physics, chemistry, biology and materials science.

The vacancy

The Synchrotron Radiation Source (SRS) Group has a vacancy for a young physicist to join the team responsible for the construction, operation and development of the SRS and for the powerful computer network which controls the machine. The Group's activities cover a wide area of applied physics often involving development work at the frontiers of technology. Further information about the post can be obtained from Mike Poole (Ext. 256) on the number shown below.

Who do we need?

We are looking for a recent graduate, of either sex, with a good honours degree in physics who could contribute to the SRS Group's challenging work programme, both as an active member of a team and as an individual using his/her own initiative. For example the person appointed would be expected to contribute to theoretical and experimental studies of the limitations imposed on beam intensity by the behaviour of electron bunches in a metal vacuum chamber.

Interested?

Applications are sought from graduates who wish to embark on an interesting and rewarding career in a field of research and development whose importance is growing rapidly. An appointment will be made at Scientific Officer level, according to qualifications and experience on a scale £2,839 to £4,415 per annum. An applicant with an upper second class honours degree and no experience might expect a starting salary of £3,294 per annum. There is a non-contributory superannuation scheme, a generous leave allowance and a flexible working hours scheme.

Closing date: 1 October 1978

To request an application form, telephone 0925-65000, Ext. 467, quoting reference number DL/638/ , or write to:

Chemical Process Development

Worthing

Two organic chemists are required to work on the development and scale-up of processes for the production of existing and prospective products at our £multi-million manufacturing facility at Worthing.

Applicants, male or female, should possess either a PhD or a good honours degree together with an awareness of current technologies. Some relevant industrial experience would be advantageous. Good communication skills are called for as close liaison will be necessary with Production, Quality Assurance, Engineering and Research departments.

We are offering competitive salaries and excellent fringe benefits including free pension and life assurance, plus outstanding sports and social facilities. Working conditions at Worthing are attractive and the laboratories are extremely well equipped with the most up to date analytical and process instrumentation.

Please telephone or write for an application form to **Mr. A. D. Caws, Senior Personnel Officer, Beecham Pharmaceuticals, Clarendon Road, Worthing, West Sussex, BN14 8QH. Telephone: Worthing 39900 Extension 233.**

ULSTER POLYTECHNIC

Faculty of Science

RESEARCH OFFICER

SCHOOL OF PHYSICAL SCIENCE

Salary Scale : £3,732 to £4,632

A Research Officer is required to assist a group working on the synthesis and bioassay of spirolactone fungicides. Applicants must have a good honours degree or equivalent in Chemistry and should have relevant research or industrial experience. Postgraduate qualifications would be an added advantage.

The Polytechnic is a direct grant institution with an independent Board of Governors. It opened in 1971 and now has a student population of some 7,100. It has extensive new purpose-built accommodation, including 750 residential places on the 114 acre campus overlooking the sea at Jordanstown, a pleasant and quiet residential area. There is a scheme of assistance with removal.

Further particulars and application forms which must be returned by October 16 may be obtained by telephoning Whiteabbey (0231) 65131 ext. 2243 or by writing to:

The Establishment Officer, Ulster Polytechnic, Shore Road, Newtownabbey, Co. Antrim BT37 0QB. 7077(A)

INVERESK RESEARCH INTERNATIONAL

RESEARCH SCIENTIST

Applications are invited for the post of Research Scientist within the section of *in vitro* Toxicology. The successful candidate will be expected to carry out established tests for transformation, mutation and DNA repair in mammalian cell cultures, to participate in research and development of new tissue culture techniques for the detection of mutagens, carcinogens and teratogens. Candidates should have a biological or biochemical background, with postgraduate experience in tissue culture, and have the ability ultimately to lead projects and supervise the daily routine within tissue culture.

I.R.I. is located near Edinburgh, within easy reach of the city and surrounding area. Relocation assistance will be provided if required and there is a full range of staff benefits. Application forms, Ref. 2314, are available from Miss J. M. Dunbar, Inveresk Research International, Inveresk Gate, Musselburgh EH21 7UB. 7111(A)

EUROPEAN MOLECULAR BIOLOGY ORGANISATION CHROMATIN WORKSHOP

23-26 March 1979

Courmayeur, Italy

This Workshop is intended as a forum for investigators working in this field (including graduate students). Numbers will be restricted. There will be a limited number of grants to defray costs of registration and accommodation. The main theme of the Workshop will be concerned with transcription and its control.

Applicants should send a brief curriculum vitae, a statement of interest in the field and, if desired, letters of support, before October 31, 1978, to:

Dr J. Paul,
The Beatson Institute for
Cancer Research,
Garscube Estate,
Switchback Road,
Bearsden, GLASGOW G61 1BD,
Scotland. 7138(A)

ST. MARY'S HOSPITAL MEDICAL SCHOOL (University of London)

Paddington, London W2 1PG
DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT GRADE 1A

required to work with Dr P. Millburn and Dr P. C. Hirom on the entero-hepatic circulation of carcinogens and anti-cancer agents.

Appointment for up to 3 years starting October 1978/November 1978. Salary within scale £3,685 to £4,611 p.a. plus £450 p.a. London Allowance, depending on age and experience.

Informal enquiries to Dr Millburn (Tel: (01)723 1252 Ext. 118). Curriculum vitae with names and addresses of at least two referees to The Secretary at above address quoting Ref RA/BIO/N. 7127(A)

Cardiac Research

A Senior appointment with ICI

Cardiac research which is one of the most important aspects of research at ICI has resulted in an extensive range of successful drugs, in particular, beta-blockers and lipid lowering agents.

We are now actively extending our cardiac research facilities to cover survival after heart attack—the survival of the myocardial cell under ischaemic conditions.

Consequently we are looking for a person to head up this project which has the full support of the Company's extensive resources. It is envisaged that the right candidate will have considerable experience in cardiac research.

You will be free to determine the approaches to be used and will lead a multi-disciplinary team of experienced researchers. You should be qualified in medicine, physiology or

pharmacology and have the ambition to further your career in research.

Remuneration and other benefits, including relocation expenses, are designed to attract candidates of high calibre. The post is based at our modern research establishment located in beautiful parkland in Cheshire. Residential, recreational and school facilities in the area are excellent.

Please reply, enclosing your curriculum vitae to:—

J W Eardley,
Personnel Department,
ICI (Pharmaceuticals Division) Limited,
Mereside,
Alderley Park,
Macclesfield,
Cheshire SK10 4TG.

7062(A)

DIRECTOR CANCER RESEARCH GROUP

The University of Western Ontario and the National Cancer Institute of Canada invite applications for the post of Director of a cancer research group. The present laboratories, which are fully equipped to undertake research on most problems in modern biology, occupy approximately 10,000 sq. ft. and are joined to the Health Sciences Centre and the University Hospital. Support for the research program and the salaries of senior staff members is provided by the National Cancer Institute of Canada. It is customary for senior staff members (usually five) to hold academic appointments, to be eligible to accept graduate students and to accept a modest teaching load. The salary will be dependent on experience and on levels prevailing at the University of Western Ontario. The deadline for receipt of applications is January 1, 1979 and the appointee could commence duties as early as July 1, 1979. Applications and enquiries should be addressed to:

Dr O. H. Warwick
Chairman, Selection Committee
c/o Office of Vice-President,
Health Sciences
University of Western Ontario
London, Ontario,
Canada N6A 5C1. 7084(A)

RESEARCH ASSISTANT or ASSOCIATE in charge of COMPUTING FACILITIES at a Medical Research Council Unit, Cambridge

The appointee will be required to manage and develop a computer system (PDP 8, 11 and 12) used for storing and analysing behavioural data, and to design and build special research equipment.

Applicants with relevant electrical engineering or electronics qualifications and some experience in one or more of these fields will be preferred.

- (i) interfacing mini computers preferably PDP's;
- (ii) using operating systems (preferably RT-11);
- (iii) computer maintenance.

Some programming ability (especially in assembler code) also an asset.

The appointment is on a Research Assistant (£2,956 to £5,058) or Research Associate (£4,365 to £5,730) scale, depending on age and experience.

Applicants should write to The Director, MRC Unit on the Development and Integration of Behaviour, University Sub-Department of Animal Behaviour, Madingley, Cambridge CB3 8AA. 7108(A)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF ZOOLOGY TECHNICIAN (ELECTRON MICROSCOPIST)

To work in the Department Electron Microscope Unit. Candidates should have experience or interest in Electron Microscopy and must possess O.N.C., H.N.C. or degree qualifications. Salary according to qualifications and experience in a range up to £3,720 per annum.

Application forms may be obtained from The Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref RV/925/N 7109(A)

UNIVERSITY OF SOUTHAMPTON

Applications are invited for NRDC funded Postdoctoral Research Assistantships in Organic Electrochemistry to develop commercially viable electrochemical syntheses using novel concepts for the trapping of reaction intermediates. This project will cover both fundamental and applied aspects. Applicants should have research experience in either organic chemistry or electrochemistry.

Salaries will be in the range £3,883 to £4,882 per annum plus U.S.S. benefits.

Applications, giving a curriculum vitae and the names of two referees, should be sent to Dr J. M. Mellor and Dr A. Bewick, Department of Chemistry, The University, Southampton SO9 5NH. Please quote Ref MA1/2/Na. 7114(A)

SCIENTIFIC OFFICER/ HIGHER SCIENTIFIC OFFICER PHYSIOLOGY DEPARTMENT

Applications are invited from recent graduates or those holding suitable qualifications for the above post. The person appointed will be required to head a small team studying the significance of various morphological and physiological attributes for the water economy of cereal crops. The emphasis in the research will be on experimentation in field plots sheltered from rain by mobile plot covers. The work will require the determination of water use by the experimental crops and studies of their stomatal behaviour and radiation balance. Applicants should have an interest and preferably experience in the physical aspects of water movement through the soil and plant to the atmosphere. They should have a 1st or Upper 2nd Class Honours Degree or equivalent in a biological subject.

The appointment will be as Higher Scientific Officer (£4,101 p.a. to £5,448 p.a.) or Scientific Officer (£2,839 p.a. to £4,415 p.a.) according to qualifications and experience. At least two years postgraduate research experience is required for appointment as Higher Scientific Officer. Non-contributory pension scheme.

Further particulars may be obtained from the Establishments Officer, Plant Breeding Institute, Maris Lane, Trumpington, Cambridge CB2 2LQ and applications, with curriculum vitae and the names of three referees, should be sent to him by September 29 1978. 7085(A)

International Pharmaceutical Company

Is looking for its R & D Division

HEAD OF PLANNING AND REGULATORY AFFAIRS

The successful applicant and his/her team will be called upon

- to study the regulatory requirements of the compounds under development;
- to maintain and develop contacts with the regulatory agencies in important countries;
- to identify areas where co-operation is required between these agencies and the company in terms of possible future regulatory requirements;
- to assist management in determining the R & D effort required for successful registrations;
- to agree the resulting planning schedules with the management;
- to follow up work and insure that forecasts are met;
- to insure the availability of the required registration material at the dates forecast in the planning schedules;
- to assume responsibility for the format and presentation of the registration dossiers as required for various governments' regulatory agencies.

He/she will have:

- previous experience in this field, and/or
- a post graduate qualification (eg M.P.S. or Ph.D.)

High salary will be offered to the successful candidate. Please reply to Box No. 7118(A), 3 Dyers Building, Holborn EC1. 7118(A)

Scottish Institute of Agricultural Engineering
SOILS SECTION

SENIOR SCIENTIFIC OFFICER/PRINCIPAL
SCIENTIFIC OFFICER (Ref. AG/18/A)

(Re-Advertisement)

Applications are invited for the post of Senior Scientific Officer/Principal Scientific Officer to lead a team investigating the effects of agricultural machinery on the physical properties of field soils with particular reference to cultivations, zero-tillage and compaction.

QUALIFICATIONS: A first or upper second-class Honours Degree, and preferably a higher Degree, or equivalent qualifications in a relevant branch of Science or Engineering. The applicant should have had considerable experience of research in soil physics or soil mechanics.

SALARY SCALES: Appointment in the grade of Senior Scientific Officer (£5,154 to £6,898) or Principal Scientific Officer (£6,609 to £8,461) according to qualifications and experience. Non-contributory superannuation.

Application forms and further information from:—

The Secretary, Scottish Institute of Agricultural Engineering,
Bush Estate, Penicuik, Midlothian EH26 0PH.

to whom applications should be submitted by October 6, 1978. 7120(A)

THE HANNAH RESEARCH INSTITUTE HIGHER/SENIOR SCIENTIFIC OFFICER

A vacancy exists for a Higher/Senior Scientific Officer in the Physiology Department, to join a team engaged in studying the mechanism and control of milk secretion.

Applicants should possess a First or Upper Second Class Honours Degree in a relevant discipline with, preferably, a Ph.D.

Salary will be in the range of £5,101 to £5,448 for H.S.O. and £5,154 to £6,898 for S.S.O. At least two years relevant postgraduate experience is required for appointment to H.S.O. and at least four years appointment to S.S.O. Non-contributory superannuation scheme in operation.

Further particulars may be obtained from: The Secretary, The Hannah Research Institute, Ayr KA6 5HL, to whom applications, which should include a curriculum vitae, list of publications, and the names and addresses of three referees, should be sent by October 6, 1978. 7139(A)

UNIVERSITY OF GLASGOW DEPARTMENTS OF SURGERY AND BIOCHEMISTRY Glasgow Royal Infirmary RESEARCH ASSISTANT

Applications are invited for the post of RESEARCH ASSISTANT in an interdisciplinary group investigating the production of foetal antigens by human tumours. The post is suitable for a graduate in biochemistry or related subject. Experience in radio-immunoassay techniques would be an advantage. The successful candidate will work in the new Department of Biochemistry, Glasgow Royal Infirmary. The appointment is funded by the Cancer Research Campaign and is tenable for one year. The salary will be within the University Research Assistant scale (£3,660 to £4,130 per annum presently under revision). The appropriate superannuation scheme applies. Starting date by agreement.

Further information can be obtained from Dr J. G. Ratcliffe, Department of Biochemistry, Royal Infirmary, Glasgow G4 0SF (Tel. 041 552 3535, extension 5275) to whom applications including curriculum vitae and the names of two referees should be sent within 2 weeks of the appearance of this advertisement.

In reply please quote Ref. No. 4241(M). 7078(A)

BEDFORD COLLEGE (University of London) DEPARTMENT OF GEOGRAPHY RESEARCH ASSISTANT Limestone Weathering in Urban Environments

Applications are invited for RESEARCH ASSISTANTSHIP to be funded by the Building Research Establishment (Garston) to initiate mainly through literature and project reviews, a study of the mechanisms of limestone weathering in urban environments. Applicants should preferably be qualified in one or more of the following fields: chemistry, geochemistry, environmental science, or physical geography; ability to read German and French an advantage. European travel possible. The appointment is initially for 6 months, and may be extended for a further 6 months.

Gross salary: £3,834 p.a.
Applications to Professor R. L. Cooke, Bedford College, Regent's Park, London NW1 4NS, by October 3, 1978. 7137(A)

FRESHWATER BIOLOGICAL ASSOCIATION WINDERMERE LABORATORY ASSISTANT LIBRARIAN/ INFORMATION SCIENTIST

Applications are invited from graduates in information science, or science graduates with a qualification in Librarianship, for the above post which is to strengthen the Association's library and information services. The post will be graded as Assistant Librarian (£3,113 to £3,579 per annum) and conditions of service will be generally similar to those of the Civil Service. Full details and application form may be obtained from the Secretary, Freshwater Biological Association, The Ferry House, Ambleside Cumbria LA22 0LP. Closing date September 30, 1978. 7025(A)

UNIVERSITY OF MINNESOTA DEPARTMENT OF ASTRONOMY Applications are invited for a POSTDOCTORAL RESEARCH ASSOCIATE POSITION

in the

Department of Astronomy

Candidates should be experienced in radio interferometry and prepared to conduct and collaborate in research using the VLA radio telescope. The appointee will be expected to establish an initial VLA map analysis system and to participate in development plan for a permanent facility at the University of Minnesota. The position is available for one year, beginning on January 2, 1979. The possibility of an extension of the appointment for a second year is under consideration.

Candidates should send a letter of application, including a curriculum vitae and bibliography, and the name of three references who have been asked to submit letters of recommendation to Dr W. B. Burton, Chairman Department of Astronomy, University of Minnesota, 116 Church St. S.E. Minneapolis, Minnesota 55455. The deadline for receipt of applications is October 31, 1978. The University of Minnesota is an equal opportunity educator and employer. 7096(A)

ODD BALLS . . .

On our register we have unusual, indeed, inimitable electronic engineers and applied scientists. Even WE have not found the right socket for some of them—yet.

COULD YOU USE

"DR X, THE SOID KID". An interesting physics/electronics hybrid with a class A brain, yet there he is, sleeves rolled up, building his own laboratory apparatus. Shades of Sir Isaac himself?

"OUR POTENTIAL DIFFERENCE". A distinctly different First Glamorous brunette, 34-24-36. Great potential in logic design or micro-processor software, a slight analogue allergy and a most definite Ph.D. phobia. Try her field effect.

"JONESY, THE WATERMILL NUT". For years he has worked with scientists translating their ideas into cost effective laboratory equipment and systems—now he's stuck on power supplies. Not the right environment for one who knows his true métier was teaching. Research Technician?

"QUANTUM QUIKOTE". A doctor but not a quack—used to the soft equilibrium of his electron cloud, not that he's ready for a Quantum jump into hard Uncertainty—Lasers or Magnetrans, over to you!

REASONABLY PRICED HARDWARE OR SOFTWARE ENGINEERS—these are gold dust. However, try our sophisticated electronic talent detectors, (Judy, Dawn and Ann) no panning techniques used here.

For further details contact:
CHARLES AIREY ASSOCIATES
LIMITED
155 Knightsbridge
London SW1
01-581 0286

NATIONAL COUNCIL FOR SCIENTIFIC RESEARCH

Applications are invited for the following vacant posts in Building Research Unit:

1. Soil Mechanics and Foundation Engineer

Qualification: Degree in civil engineering and relevant experience.

Duties: To undertake soil surveys and site investigations with percussion and rotary drilling rigs and laboratory testing of soils for foundation works.

2. Materials Engineer/ Scientist

Qualifications: Degree in Materials Engineering Science with a minimum of five years experience in research and development work.

Duties: Successful candidate will be required to initiate and carry out research and development work on the utilisation of local raw materials in the production of soft boards or development of alternative roofing materials for low cost housing, and to provide technical advice on the production and usage of building materials.

The above-mentioned post are required to be filled immediately and not later than April 1979.

Salary will be according to qualifications and experience on the following scales:

Senior Principal Professional Officer: K7,812 by 204 to K8,016 by 216 to K8,232.

Principal Professional Officer: K6,756 by 216 to K6,972 by 288 to K7,200 by 204 to K7,608.

Senior Professional Officer: K5,424 by 288 to K5,712 by 300 to K6,012 by 312 to K6,324.

Applications giving full personal details, qualifications and experience and names and addresses of three referees should be submitted to:

The Secretary General,
National Council
for Scientific Research,
P.O. Box CH 158,
Lusaka,
Zambia.

UNIVERSITY COLLEGE OF NORTH WALES

Bangor

Applications are invited for the post of
LECTURER

IN MARINE CHEMISTRY

Applicants should have a good Honours Degree and experience and/or interests in inorganic solution of chemistry. Previous experience in the chemistry of sea water and/or natural waters would be an advantage.

The successful applicant will be expected to contribute to teaching undergraduate and postgraduate related courses, and to undertake research in the field of marine chemistry.

The appointment, commencing on October 1, 1978, or as soon as possible thereafter, will be to the lower portion of the scale £3,883 to £7,754 per annum.

Applications (two copies), giving details of qualifications and experience, together with the names and addresses of three referees, should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG, from whom further particulars may be obtained.

Closing date for applications: October 2, 1978. 7133(A)

AN FORAS TALUNTAIS

requires a

Agricultural Science Graduate

at it's Moore Park Research Centre, Fermoy, Co. Cork, to undertake research on the development of intensive dairy farming systems with particular emphasis on grass-land production and utilisation.

ESSENTIAL: An Honours University Degree or equivalent in Agricultural Science.

DESIRABLE: Suitable research experience.

Appointment up to and including Principal Research Officer level depending on qualifications and experience. Marriage and children's allowances, Non-contributory Pension Scheme and provision for widow's and orphan's pensions.

Application forms and further particulars available from the Personnel Department, (quote ref: Mor), An Foras Taluntais Headquarters, 19 Sandymount Avenue, Dublin 4. (Phone: 688188). Latest date for receipt of completed forms, Monday October 13, 1978. 7079(A)

AGRICULTURAL RESEARCH COUNCIL

Plant Physiologist

Applications are invited from Plant Physiologists who would like to join a small team of senior scientists who advise the Secretary of the Council on the scientific aspects of research administration.

The post is graded Senior Principal Scientific Officer with a salary scale of £10,043-£11,300 plus £465 for working in Central London. Superannuation is under a non-contributory scheme analogous to that of the Civil Service.

Applications from candidates with a good honours degree or equivalent qualification and a successful record of research should be by letter accompanied by a full curriculum vitae and the names of two referees.

Further particulars from Miss M. J. Gard,
Agricultural Research Council,
160 Great Portland Street,
London WIN 6DT.
Closing date: 20 October 1978.

FELLOWSHIPS

SENIOR VISITING FELLOWSHIP PROGRAM

Centre for
Interdisciplinary Studies
in Chemical Physics
The University
of Western Ontario
London, Ontario,
Canada N6A 3K7

The Centre for Chemical Physics at The University of Western Ontario invites applications for its Senior Visiting Fellowship Program from established scientists working in areas that bridge two or more of the disciplines of applied mathematics, physics, chemistry, engineering, botany, biophysics, nuclear medicine and radiation oncology. The Fellowships are tenable for a period of up to 12 months, and provide funds for travel, partial or complete living support at U.W.O., and some research support. During the tenure of their Fellowships, visitors will be expected to work in conjunction with Centre members.

Interested persons are asked to write to:

8/8/78 The Chairman, Visiting
Fellows Committee,
Centre for
Interdisciplinary
Studies in Chemical
Physics,
The University of
Western Ontario,
London, Ontario,
Canada N6A 3K7

for application forms and additional
information. Applications for 1979
must be received no later than
December 15, 1978. 7081(E)

TWO POSTDOCTORAL FELLOWSHIPS IN THE EARTH AND PLANETARY SCIENCES

The Lamont-Doherty Geological Observatory of Columbia University invites scientists interested in any field of the earth and planetary sciences to apply for the following Fellowships.

Two Postdoctoral Fellowships, each awarded for a period of one year (extendable to two years in special instances) beginning in September, 1979, with a stipend of \$16,500 per annum. Completed applications are to be returned by January 15, 1979. Application forms may be obtained by writing to the Director, Lamont-Doherty Geological Observatory, Palisades, New York, USA 10964.

Award announcements will be made February 28, 1979. 6099(E)

Southampton THE UNIVERSITY

THE HARTLEY FELLOWSHIPS

Applications are invited for three Fellowships normally tenable from October 1, 1979, for up to two years research, in any field for which facilities are available within the Faculties of Arts, Science, Engineering and Applied Science, Social Sciences, Law, Education, Medicine and Mathematical Studies.

Fellows will normally be appointed from persons of high promise whose records show evidence of capacity for original research, and who have up to five years postdoctoral experience or equivalent research record.

Salary will be related to age and experience and be within nationally agreed ranges for research staff in universities. (No provision for travel or removal expenses).

The closing date for applications for the 1979 competition is November 1, 1978.

Details and application forms from Mr E. D. Gordon, The University, Southampton SO9 5NH. Please quote ref. MA/1/Na. 7076(E)

UNIVERSITY COLLEGE OF WALES Welsh Plant Breeding Station

Applications are invited for a

RESEARCH FELLOWSHIP

commencing November 1, 1978 to work on the use of multiline varieties of barley for the control of barley mildew.

The fellowship which is funded by the Home Grown Cereals Authority, will be given for three years, and will carry an allowance of £3,254 to £3,527 per annum.

Applicants should have postgraduate experience in plant pathology, preferably in epidemiology.

Applications together with curriculum vitae and the names of three referees should be sent to the Secretary, Welsh Plant Breeding Station, Plas Gogerddan, Aberystwyth, Dyfed, by Monday, October 2, 1978, from whom further details are available on request. 7086(E)

IMPERIAL CANCER RESEARCH FUND RESEARCH FELLOWSHIP

A Postdoctoral Fellow required as soon as possible for an appointment of two years with possible extension to three years. The work will be on the mechanisms by which host cells control the expression of tumour-inducing viruses. Preference will be given to candidates familiar with nucleic acid hybridisation and allied techniques.

Salary with entry according to qualifications and experience within range £4,815 to £6,180 incl.

Applications with curriculum vitae and names of two referees, should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX by October 27, 1978, quoting reference 263/78. 7059(E)

UNIVERSITY OF SOUTHAMPTON DEPARTMENT OF OCEANOGRAPHY

Applications are invited for a POSTDOCTORAL FELLOWSHIP

to work on plankton photosynthesis in an estuary. The successful applicant will be expected to undertake field and theoretic studies to develop a model for photosynthesis for the Medway Estuary. The work will be undertaken in conjunction with the Water Research Centre. The fellowship will be tenable from October 1, 1978 to December 31, 1979.

Applications, giving the names of two referees, should be sent as soon as possible to Dr P. J. Williams, Department of Oceanography, The University, Highfield, Southampton SO9 5NH, from whom further particulars may be obtained.

Salary range: £3,883 to £6,080 per annum plus U.S.S. benefits.

Please quote ref. MA1/2/Na. 7088(E)

THE UNIVERSITY OF SHEFFIELD POSTGRADUATE SCHOOL OF LIBRARIANSHIP AND INFORMATION SCIENCE JUNIOR

RESEARCH FELLOWSHIP

Applications for the above post are invited from men and women graduates with good honours degrees interested in undertaking research in librarianship or information science. The Fellow will be required to undertake light teaching duties, and to undertake research (towards a Ph.D. degree). The School's research interests are wide.

Tenable annually for 3 years, initial salary in range £3,189 to £3,895 a year.

Particulars from the Registrar and Secretary, The University, Sheffield S10 2TN, to whom applications (5 copies) should be sent by October 9, 1978. Informal enquiries to Professor M. F. Lynch, P.G.S.L.I.S. Quote Ref. R197/G. 7121(E)

STUDENTSHIPS

UNIVERSITY OF WARWICK RESEARCH STUDENTSHIP IN BIOCHEMISTRY

Applications are invited for a three-year research studentship in the Department of Chemistry and Molecular Sciences, sponsored by the Science Research Council under the C.A.S.E. scheme. The project, with Dr B. E. P. Swoboda will involve study of the mechanisms of action of cytosine arabinoside, currently used in cancer chemotherapy including the effects of the drug on DNA synthesis. Candidates must possess either a first class or an upper second class degree in Biochemistry or a related subject. Applications (two copies) giving qualifications and experience and naming two referees should be sent to the Academic Registrar, University of Warwick, Coventry CV4 7AL, as soon as possible, quoting Ref. No. PG/5/71 7082(A)

SCHOLARSHIPS

THE ROYAL SOCIETY GOVERNMENT GRANT FOR SCIENTIFIC INVESTIGATIONS

Applications for grants from the third allotment of the Government Grant for Scientific Investigations for the year 1978 should be made not later than November 15, 1978 on forms of application to be obtained from the Executive Secretary of the Royal Society, 6 Carlton House Terrace, London SW1Y 5AG.

Applicants must be British subject domiciled in the United Kingdom. Grants made be made to promote an support research in science and to assist scientific expeditions and collections; but not for personal maintenance, payment of stipends or to aid scientific publications. 7116(H)

THE ROYAL SOCIETY SCIENTIFIC PUBLICATION GRANT

Applications for grants from the second allotment of the Scientific Publications Grant for 1978 should be made not later than November 8, 1978 on forms obtainable from the Executive Secretary, The Royal Society, Carlton House Terrace, London SW1 5AG. The grant is for the assistance of scientific publications in the United Kingdom, particularly, but not exclusively, those of scientific societies and institutions.

Applications are receivable only from societies and institutions in the United Kingdom and individuals of British nationality. 7115(H)

HIGHEST STANDARD OF QUALITY IN BIOLOGICAL REAGENTS FOR THE STUDY OF NUCLEIC ACIDS, SYNTHESIS AND PROCESSING.

		PRICES
RIBONUCLEASE PHY I (Cat. No. ERN-PHY) (RNase I' from Physarum Polycephalum) This novel enzyme preferentially digests G, A and U residues allowing discrimination between C and U in RNA sequencing by the gel method.	Free from other Ribonuclease and Phosphatase activities.	145.00/100 units
T4 POLYNUCLEOTIDE KINASE (Cat. No. EPN-4) (RNase-free) Prepared from T4-infected RNase I' E. coli, specifically labels 5'-OH termini of RNA and DNA chains. With this product, kinase labelling of small quantities of large RNA's for sequencing is possible for the first time.	Free of nucleases.	75.00/100 units 315.00/500 units
T4 RNA LIGASE (Cat. No. ERL-4) (RNase and DNase-free) The enzyme is capable of adding single residues (in the form of pNp) to 3' termini of the RNA chains, allowing sequence analysis by the gel method. Ligase From RNase I' E. coli allows application of this approach to a variety of large RNA's species.	Specific Activity 2000 units/mg Completely Free of RNase and DNase Activities	60.00/100 units 235.00/500 units
TERMINAL TRANSFERASE (Cat. No. ETT-C) (from calf thymus) Suitable for addition of polynucleotides to an appropriate primer, or a single addition of a nucleotide at 3' end to create products suitable for DNA sequencing (procedure for a single nucleotide addition is provided by request).	Specific activity 50,000 units/mg Completely free of DNase activity	98.00/500 units 195.00/1000 units
ALKALINE PHOSPHATASE (Cat. No. EAP-1) (from E. coli BL 15 RNase I') This preparation is free of any detectable RNase or DNase activities.	Specific activity 140 units/mg.	65.00/100 units 120.00/250 units
DNA POLYMERASE I (Cat. No. EDP-1) (Kornberg polymerase) From E. coli BL 15. For analytical and preparative purposes Suitable for nick translation of DNA in vitro.	Specific activity 15000 units/mg Free of DNase and Exonuclease III	155.00/250 units 275.00/500 units
EXONUCLEASE III Cat. No. EEX-III This enzyme digests double-stranded DNA from 3' end and yields single-stranded DNA.	Free of endonuclease I or II. Not less than 35000 units/mg.	60.00/250 units 95.00/500 units

Molecular Biology Enzymes For Synthesis

- 0880 RNA LIGASE (T₄ inf. *E. coli*)**
 For synthesis of oligonucleotide with specified 3' terminus and other applications, see P-L Abstracts 6 (2) April 1978.
New Lower Price 150 units\$60.00*
- 0872 DNA LIGASE (NAD, *E. coli*)**
 λ lysogenic system
 New technology permits 90% lower price.
New Lower Price 2500 units\$50.00*
- 0429 POLYNUCLEOTIDE PHOSPHORYLASE TYPE 15**
 (*M. luteus*)
 Old favorite for polyribonucleotide synthesis, phosphorolysis, arsenolysis.
New Lower Price 30 units\$33.00
- 0916 RNA POLYMERASE (*E. coli*)**
 This new product with a specific activity >800 units/mg is nuclease free.
New Low Price 80 units\$ 60.00*
400 units\$240.00*
- 0870 DNA LIGASE (T₄ inf. *E. coli*)**
 New process yields quality product at reduced price.
25 Weiss units (500 P-L units)\$55.00*
 *Insulated container and refrigerant charge \$6.00.

'AnalaR'... from BDH

Nobody does it better
(that's why we have to be so good!)

'AnalaR' is the registered trade mark of AnalaR Standards Ltd.

A high-magnification micrograph showing the characteristic 'peacock' pattern of opal. The image displays a dense, repeating array of dark, roughly circular or hexagonal domains, which are the silica spheres, separated by lighter-colored, irregular gaps. The overall texture is granular and highly ordered, illustrating the long-range periodic arrangement of the spheres.

Cytotoxicity Testing

The Titertek Supernatant Collection System

Cellular cytotoxicity assays can be performed quickly, economically, and safely with the Titertek Supernatant Collection System. Designed to facilitate the harvesting of supernatant from a standard Titertek/Linbro 96-well, U-shaped microtitration plate, the Titertek Supernatant Collection System separates the cellular components of a culture from the supernatant. Only the isotope released into the supernatant is collected.

- The Titertek Supernatant Collection System is . . .
- Quick** Harvests 96 wells in less than 30 seconds; eliminates centrifugation of plates;
 - Accurate** Collects approximately 90% of supernatant, uniformly absorbs it, avoids traumatization of cells during collection;
 - Convenient** Does not remove cells during supernatant collection; Eliminates cross-contamination between wells; Prevents buildup of isotopes in equipment
 - Economical** Collects most of the supernatant, permitting the use of fewer target cells and less radioactive label.

We'll be specific

Receptor-specific proteins are valuable reagents in cell studies because of their well-defined interaction specificities. You must be able to rely on them being pure, biospecific and fully active. You can when you purchase your receptor-specific proteins from Pharmacia Fine Chemicals.

		<i>Specific for:</i>
	Concanavalin A*	D-Glucose/Mannose
	Soybean Lectin	N-acetyl-D-Galactosamine
New	Lentil Lectin*	D-Glucose/Mannose
	Wheat germ Lectin*	N-acetyl-D-Glucosamine
New	Helix pomatia Lectin*	N-acetyl-D-Galactosamine
	Protein A (<i>S. aureus</i>)*	F _c region of immunoglobulin G
New	FITC-Protein A	F _c region of immunoglobulin G (fluorescent, for microscopy)

*Also available immobilized on Sepharose®, for use in affinity chromatography.

Biospecific interaction between a receptor-specific protein and its corresponding ligand – the property important for your experiments – is the mechanism behind its purification using affinity chromatography, separating it from inactive contaminants. Pharmacia

Fine Chemicals are leaders in affinity chromatography and our long experience in this technique is exploited in the production of our receptor-specific proteins. You get proteins which are pure, biospecific and fully active. Freeze-dried and salt-free. Ready for use on reconstitution with buffer.

Can we be more specific? Contact your usual supplier of Pharmacia products for further information on receptor-specific proteins.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures.

Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to e^a if '*a*' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976).

First things first in the Third World

AS THE national papers pile up in the headquarters of the United Nations Conference on Science and Technology for Development due now in less than a year's time, the pace of international meetings preparatory to the conference also grows. One of the most interesting, because of its wide ranging geographical representation, particularly of socialist countries, has been that organised by the World Federation of Scientific Workers in conjunction with the Union of Algerian Engineers and held in Algiers last week. The gathering, the responsibility of Professor J. M. Legay, showed rather clearly both the strengths and weaknesses of calling an international meeting to discuss a subject so large and so open to wide differences in interpretation.

Let us dispose of the weaknesses rapidly in order to concentrate on the strengths. The contribution to the conference by members of developed socialist countries was largely disappointing. Many from other parts of the world must have looked forward to discussion of socialist policies on development; they were given only vague theorising and totally uncritical self-advertisement in papers of almost uniform tedium. Example "The mission of structuring the overall problematique of social development into development complexes is to facilitate decisions in situations when concrete variants of sectoral development have to be derived from strategic goals or generally formulated concepts".

If there is one message that ought to get back to the governments of socialist countries—and indeed of many capitalist ones too—it is that the preparations for UNCSTD are making many scientists and technologists of the developing world much more critical of the statements of developed nations, and meaningless, self-satisfied or jargon-ridden papers will cut little ice.

That said, it is pleasing to be able to report that contributors from developing countries, and a few non-socialist countries, did have some significant and provocative things to present. It was clearly a hope of the organisers that the meeting would shed some light on scientists' responsibilities in the establishment of the New International Economic Order, that concept which also emerged from Algeria just five years ago and which is espoused with enthusiasm throughout much of the Third World as a way, *inter alia*, of obtaining control over natural resources and exerting more influence on the global monetary system. This new order is, however, not mentioned much in the capitalist world; as Professor E. H. S. Burhop, president of the Federation, put it, "the

overwhelming majority . . . in the industrialised capitalist countries . . . have never heard of the new order and are quite unprepared for the vast economic changes in their own countries it implies". The contributions that made the most impact, however, were not those that concentrated on praising the new order, or for that matter reviling the multinational corporations. Most effective were those papers that took a hard look at real problems in the developing world, admitted mistakes rather than tried to dole out blame, and made positive proposals for the alleviation of difficulties.

Two issues of importance seemed to emerge. The first was the very serious problem of effective use of intellectual resources in the developing world. Higher education in the Third World is easily seen as a status symbol, by governments and people alike. The more universities, the more PhDs, the closer the resemblance to western seats of learning, the better. But the further this path is trodden, the less it seems that trained scientists and technologists have an understanding of what people's needs are. This, of course, is not a phenomenon exclusive to the developing world, but whereas in the developed world we may have the luxury of debate as to how "relevant" university education need be, such a discussion in the developing world must surely be subservient to very visible national needs. And yet India, with more than a million technically qualified people, hardly seems to have harnessed this resource at all, and, in the words of a Pakistani participant, the role of science in the development of his country "has not been very significant".

There are many factors that have apparently contributed to a detachment of education from urgent national needs in many developing countries. The siren-call of developed-world science diverts too many into vain attempts at imitation. Poor experimental facilities drive many a good scientist into rather sterile theory. Service to the community through the provision of better water supplies or more efficient energy use is not seen to be very prestigious. There is a pressing need for those concerned with national science and educational policies to recognise that higher education and scientific research establishments can best serve development not by mimicry of the developed world but by a long cool consideration of local, often rural conditions where the potential for science-based improvements is still enormous.

The second issue of importance to come from the conference was that development which simply results in more

jobless cannot be acceptable. Higher productivity can well lead to unemployment, so it is most important that the aim, particularly within the rural sector, should not be for a mighty technological revolution which releases vast numbers of agricultural workers to flock to cities incapable of receiving them. The abundant manpower resources of many developing countries have to be handled with the greatest of care. One Bangladeshi contribution put this very succinctly: "in most cases our object is to upgrade simple rural technology to a slightly higher level of sophistication which improves the quality of life for the workers and creates more job opportunities." The emphasis, then, is on modest aims and on evolutionary development. In a notably thoughtful contribution, Dr H. Harada, Deputy Assistant Director-General for Science at Unesco, drew attention to the need to accept a slow and deliberate pace, in which a nation is at pains to develop science ahead of technology.

So what comes from such a conference? A final docu-

ment, necessarily general, of course. But maybe the germs of something more substantial. Numerous participants, while recognising that no New International Economic Order will come about without a correspondingly new national order, note nonetheless that there is enormous scope for international research centres to cope with developing world problems. Few of these problems respect national frontiers, nor are they such that questions of commercial secrecy should be involved. If there can be an International Centre for Theoretical Physics, specifically aimed to assist developing countries, is there not some sense in international, maybe regional centres on other scientific matters perhaps of a more immediate concern to development? A few exist already, of course, notably through the Canadian initiative of the International Development Research Centre, but there was little doubt in people's minds at Algiers that there was scope for more. As David Dickson reports on the following page this mood now seems widespread. □

Multinationals and development

Multinational corporations often come under criticism for their involvement in the developing world. But, argues Lewis Branscomb, Vice President and Chief Scientist of IBM, multinationals make major contributions to indigenous development.

THE United Nations Conference on Science and Technology for Development (UNCSTD) will look at the urgent need for indigenous capabilities in both developed and developing nations to mobilise science and technology in the cause of human problems. Poorer nations are understandably impatient with the slow and expensive process of institution building out of which emerged the education, research and industrial enterprises of the industrial democracies. But without the capacity to absorb, adapt and exploit technical knowledge, no amount of documented knowledge, patent licences or computer access will produce the economic results that are needed. How can this capacity be built?

National assistance agencies, international banks and private foundations can do a lot more than they have. Technical assistance programmes should be separated from security and capital assistance. Every prosperous nation has to find its own way to focus the energies of its universities and private sector establishments on institution building in cooperation with less developed countries. President Carter has made a farsighted proposal in his speech in Venezuela, proposing a government-sponsored foundation for technical cooperation to deal with this long-term need of the developing world.

Technical cooperation in education and research can look after many basic human needs, but industrial capability is only built up very slowly in this way. What is a more direct route? The fastest way to transfer technical capability from one nation to another is by exchange of the people with skills and experience, tools and procedures, and (when required) their financial resources and foreign market access. American industrial technology was built by direct foreign investment by European firms in Victorian times. Research was little known in 19th century American universities; the nation's industry was craft-oriented. Most of the population was in agriculture, which based its productivity more on the expanse of unexploited fertile land than on the cropping technology of Europe.

Why then are today's industrial enterprises which are

engaged in technologically-sophisticated operations in many countries (the "multinationals") so often regarded as part of the problem, when in fact they are a part of the solution?

When a responsible, modern multinational starts a business operation in a host developing country, it contributes to indigenous technical and managerial development in many ways. For example:

- By hiring and training host-country nationals for all levels of employment in the national subsidiary. Education and experience in industrial operations is gained in the community and is made successful under local conditions.
- Through technical cooperation of the multinational's local manufacturing plants with its plants and laboratories in other nations, a broad base of technical support is available in the event of technical difficulties.
- By obtaining materials, parts and assembly from local suppliers (IBM has 80,000 such vendors worldwide), a great deal of technological knowledge and experience is transferred, as the local company of the multinational works with each vendor to assure quality control of the product.
- As local skills develop and local markets justify expanded investment, more complex products can be undertaken by national subsidiaries and access to international markets expanded. In this way multinationals make important contributions to the balance of trade in many developing countries.
- Many products, such as communications equipment, trucks, machine tools and computers, not only contribute to national wealth directly but have large secondary benefits because their use in other sectors can increase productivity in the economy as a whole.

Sovereign nations must certainly look after the interests of their citizens by determining the rules regarding investments of skills and money within their borders. It is important that the leaders of those countries avail themselves of technical advice from those with industrial experience, to ensure that policies driven by economic objectives take into account technological realities. Transferring technology, even within the component parts of a single American or European enterprise, is not easy and requires time, training and extra expense. But above all it calls for a cooperative attitude by all the participants.

Let us hope that this is the outcome of the 1979 conference. □

The United Nations conference on Technical Cooperation between Developing Countries, which ended in Buenos Aires (right) last week, was a great success for third world countries, writes David Dickson

Camera Press

Developing countries to boost joint research

JOINT research projects between two or more developing countries are to receive greater emphasis, according to an ambitious 'plan of action' adopted last week by 138 member countries of the United Nations Development Programme. The plan was the main result of the conference on technical co-operation between developing countries (TCDC) which ended last week in Buenos Aires, Argentina.

The plan of action is based largely on suggestions made to the conference by the so-called 'Group of 77'—comprised now of 114 developing nations. The plan suggested that developing countries should "encourage existing national research and training centres to broaden their scope of activities to include programmes and projects which are of interest to several countries at a sub-regional, regional, and inter-regional level".

The conference also accepted a resolution submitted by Jamaica on behalf of the Group of 77 urging all developing countries to cooperate in strengthening existing research and training centres, with the intention of giving them "a multinational scope in the framework of TCDC" and where necessary establishing new institutions to achieve these ends.

And in order to prevent the plan of action being shelved as a well-meaning but ineffective document, the conference included in its recommendations specific directions for the way in which TCDC is to be encouraged and propagated, both within and outside the UN system.

Thus while rejecting as unnecessarily bureaucratic the idea of a new UN body with specific responsibilities for TCDC issues, the plan of action directs the UNDP to organise regular meetings—initially annual, subsequently biannual—or the planning ministers of member states to discuss progress towards TCDC goals.

Significantly the plan indicates that funds currently allocated by UNDP for regional use should now be devoted "to the maximum extent possible" to TCDC projects. Funds allocated to inter-regional or global projects could be used for TCDC projects proposed

by two or more countries from different regions.

The significance of these decisions is that, while using international funds, the developing countries will be able to exert greater control over the way that money for technical projects is spent rather than the major impetus for the use of such funds coming from the developed countries.

Many delegates to the conference felt that the agreement on a regular meeting of planning ministers and the shift in the balance of control over technical projects had resulted in greater success for the conference than had previously been expected.

"The consensus that the conference was able to achieve on the plan of action represents a major victory for the developing countries", said Mr Abdel Razzak Meguid, Minister of Planning for Egypt and chairman of the main committee of the conference secretariat, in protest at the weakness of proposals put forward in an earlier draft of the plan.

"We have succeeded in making it acceptable to the North that it is in their interests to strengthen the 'horizontal' links between developing nations. That bridge is now not only accepted as a hope, but as a necessity if the world community is to survive".

However, few speakers at the conference pretended that TCDC was a new strategy. Background papers prepared for the conference, for example, described the complex network of overland trade routes that had existed between different countries in Africa before the arrival of European traders and colonialists.

Furthermore there has in recent years been a steady growth in joint research projects between various developing countries. The University of Chile, for example, is now co-ordinating a Latin American scheme for co-operation in postgraduate teaching and research in the biological sciences, which has already set up studies in areas such as the spread of plant viruses and the biological effects of working at high altitudes (such as in the mines of Peru).

What many delegates felt was new,

however, was the emphasis that the conference was able to place on the concept of TCDC not merely as defined by a limited set of bilateral or multilateral agreements, but as a basic strategy for achieving the goals of what has come to be known as the 'new economic order' and the joint attempts of developing countries to counter the economic dominance of the developed world.

Thus initially the conference had been conceived in relatively narrow terms as dealing primarily with issues relating to technological co-operation, partly at the instigation of the more advanced of the developing nations, many of whom—such as the host country Argentina—are looking for new outlets for their goods and technical services.

However, during the evolution of the conference, the concept of TCDC has gradually become much broader, covering radical approaches to education and research, through to strengthening transportation, communication and information links among developing countries.

"Since agreeing in principle on the need for a 'new economic order' in 1974 the United Nations has not done a single thing to translate a programme of action into an actionable programme. But I think that this conference has laid the framework for such an actionable programme" Mr Meguid said after the plan had been accepted by the conference.

Other delegates were similarly confident that the plan, which will now be placed before the General Assembly of the United Nations, provides a firm basis for a substantial shift in control over the content of development programmes from the developed to the developing nations, and that the regular meeting of planning ministers will provide considerable support for this trend.

As far as scientific research is concerned, the conference did not consider in detail any particular programmes or list of priorities, and many of the participants from specialised UN agencies such as the World Health Organisation and the Food and Agri-

cultural Organisation had to remain primarily as observers—much to the frustration of some who claimed considerable practical experience in the issues under discussion.

However, the plan of action makes a number of suggestions about how research should be conceived within the TCDC framework. For example, it speaks of the need for developing countries to combine research efforts

and share results “both with one another and with other developing countries by means of agreements on scientific and technological co-operation, strengthening national design, national laboratories, research centres and scientific and other institutions”.

Putting flesh on these ideals will be one of the main objectives of next year's United Nations Conference on Science and Technology for Develop-

ment, which will take place in Vienna. But many delegates left Buenos Aires with the feeling that despite internal differences, the developing countries have found in the issue of technical co-operation a way in which they can work together in presenting concrete demands to the developed world, and that this in itself was a major step in bringing the new economic order closer to reality. □

US geneticists look to Europe for research facilities

RESEARCHERS at Genentech Inc, San Francisco, claimed at a Munich conference last week that they have induced bacteria to synthesise the two separate amino acid chains of human insulin—and to have combined these chains to make minute quantities of the hormone. Last year, the same team used a similar technique to induce bacteria to produce the hormone, somatostatin, and earlier this year, another team led by Walter Gilbert of Harvard University announced that they had persuaded bacteria to produce rat pro-insulin attached to the bacterial enzyme penicillinase.

Synthesis of the artificial insulin gene used by Genentech began at City of Hope Medical Centre, California late last year. Researchers there synthesised artificial genes consisting of the DNA sequence corresponding to the amino acid sequence of the A and B strands of human insulin. Six months later, they turned the synthetic genes over to David Goeddel and Dennis Kleid, biochemists at Genentech.

Goeddel and Kleid inserted the synthetic genes for the two strands of insulin into plasmids which were then introduced separately into *Escherichia coli*. The bacteria replicated and expressed the genes as the A and B amino acid chains. These were then mixed to produce a fraction of a milligram of insulin which, it is claimed, is similar to human insulin.

Biological tests for the activity of insulin, however, have yet to be done. Even though chemical tests and radio-immunoassay have indicated the presence of the molecule, some researchers question the claim that the insulin produced is the chemical equivalent of human insulin. This is because radio-immunoassay cannot distinguish between different insulin varieties. Also, the B-peptide chains produced during the recent work are impure, and some researchers feel that the amino acid analyses conducted so far may be insufficient to establish the presence of

the desired sequence.

The development of a new source of insulin for the treatment of diabetes has great practical importance. About 5% of diabetics are allergic to the animal insulin now used, and each patient requires 10 bovine pancreases per year at a cost of more than \$100. Bacterially produced insulin should eliminate allergic reactions and may be cheaper and easier to supply than animal insulin. Before the newly produced insulin could be marketed, however, it would have to undergo extensive animal and human tests which could take two to five years, though Genentech president Robert Swanson foresees no real difficulties in scaling up the procedure and passing the tests.

Such rapid success in developing a practical application of a technique raises a host of questions. The technique was discovered so recently that the original patent application has not yet been processed, and neither have revised safety regulations been implemented. Already the race for other commercial applications is hotly contested. New patents have been applied for, the breadth of the original patent remains unclear, and several leading American researchers are reportedly setting up shop in Europe to escape regulatory delays.

The original research leading to the procedure used in synthesising artificial genes was conducted with funds from the National Cancer Institute, the

National Science Foundation, the National Institutes of Health, the University of California and Stanford University. All parties eventually agreed that NIH would enter an institutional patent agreement with Stanford University and the University of California. Stanford would administer licensing of the technology, under terms of the agreement and share royalties equally with the University of California. After public hearings last spring, NIH granted Stanford permission to go ahead with licensing, provided any company granted a license would abide by NIH safety guidelines for genetic engineering.

Niels Reimers, Stanford's manager of technology licensing says he expects a patent to be issued within a matter of months, and believes it will cover much of the basic technique for producing recombinant DNA in *E. coli*. Stanford will probably wait until the patent is actually issued to begin licensing.

Such a patent would apply only in the United States. For that reason, and because of early stringent regulations, some scientists who are trying to create insulin by isolating and transferring a human gene have gone to Europe to work. Applications to use the country's first super-secure “P-4” facility, at Fort Dietrick, Maryland, will not be processed until later in the autumn. New, less stringent safety guidelines will also not go into effect until later this year.

William Rutter, a molecular biologist at the University of California, San Francisco, is already looking to Europe as the place to continue his work on the human gene for insulin. “One is forced to do that if one wants to do the experiments” he says. His group is planning to work in France. The potential advantage of using the natural gene for insulin, he says, is that it includes additional information for folding and joining the A and B peptide strands.

“Yes, we go both ways now”

Antonino Zichichi: shy of the camera, but not of politicians

Sicily's scientific evangelist

The European Physical Society, which meets next week in York, has for its president a Sicilian very powerful in Italian science politics: Professor Antonino Zichichi. He spoke recently to Robert Walgate

ANTONINO Zichichi, 48-year-old son of a Sicilian small businessman, entered university without knowing that physics could be a career. Now he is Professor of Advanced Physics at the University of Bologna. He is also virtually king of Erice, a Sicilian hill-top village where 15 years ago he established a summer school: the Ettore Majorana Centre. (A hundred scientists a week now visit Erice. "I had left Sicily. I felt guilty. I wanted to help.") Zichichi has also helped the Italian National Nuclear Physics Institute (INFN), of which he is president. Earlier this month he succeeded in doubling its budget, committing Italy to three new accelerators: an electron storage ring, a superconducting cyclotron, and an electron linac.

Professor Zichichi is a particle physicist who keeps company with the Italian ministers of science and education. And he is now President of the European Physical Society. He is also, without doubt, a thoroughgoing romantic. He is romantic about Europe. He is romantic about science. But both romances are tinged with realism: he wants to get things done.

'Culture' is an important word in his vocabulary. By it he means largely disseminated 'pure science'. Technologists, he says, are "culturally 300 years in the past; they should understand quantum electrodynamics". According to Zichichi, scientists create "new culture". "The greatest three things that mankind has created are first language, then logic, and finally science". Language needs very little logic, just enough for internal consistency. Logic,

invented 2,000 years ago, "is above language; it is something new." The most rigorous form of logic is mathematics; but you can invent anything in it, such as spaces of 25 dimensions. Science, which began with Galileo, is the logic of nature. "Science tells you if you want to believe something just ask nature. It took 2,000 years to learn that force was proportional to acceleration and not to velocity, because the Greeks only argued". Thus Zichichi believes that science is the highest achievement of mankind.

"But science has no impact in human culture. Human culture is still dominated by language. People can still be influenced by a slogan. Invent a slogan and you will have millions of people following you. A slogan is an insult to human intelligence." Science, says Zichichi, "has produced a lot of science but very little culture." What would be poetry "if poets had kept their work only in a closed drawer, or communicated only among themselves? Or painting if Raphael or Picasso had kept their paintings locked away? Or music if musicians had played only to each other? With science it's the same story. There are immense treasures of knowledge locked away in our laboratories and our libraries, but scientists have done very little to make them known to everybody."

There is a barrier to cross in that one has to work to understand science; but 300,000 years ago probably very few people had language. Using a language is not easy; but now everyone can speak. Why? Because we hear

speech from birth. "My conviction is that the same should happen with science. One day everybody will be scientists—not in the sense that they will make discoveries, but they will understand the discoveries that others are making, which is already a very great step forward".

Professor Zichichi is not unaware of the more temporal benefits of publicity. I was interviewing him at CERN, the European nuclear physics laboratory near Geneva, where he has spent most of his career since 1956. I asked him what he considered his greatest contribution to physics. It was the discovery of the antideuteron—a nucleus consisting of an antiproton and an antineutron—which he made in one night in 1965. "If you forgot the accepted wisdom about invariance principles and just thought classically, you could ask who told us that the antiproton and the antineutron stuck together like the proton and the neutron? And if they did not, the whole route to the anti-nuclei would have been stopped." Zichichi found the antideuteron. "And we didn't make any press release—nothing." Seven years later another group rediscovered it and published it widely. "At this point I decided to take more care of public impact".

Zichichi began to write for an Italian newspaper — "the greatest", *Corriere della Sera*, in a column titled 'new culture'. "I don't like to call it science popularisation". After two years he moved to *Il Giornale Nuovo*, to reach a new public, and now he writes articles of up to 1,000 words for the Saturday edition of the Rome newspaper *Il Tempo*. The latter has a circulation of 300,000, half that of his first paper, but it is read by "political people, religious people, in Rome". It is therefore more influential; and Zichichi gets more letters about his *Il Tempo* articles than any others.

If communicating science is one of Zichichi's passions, then so also are people. He sees European Physical Society first in terms of creating friendships; he sees his negotiations with ministers in terms of relationships and conversations, as a matter of convincing individuals face-to-face with his arguments. "I like to leave the administration of INFN to those who can do it better than me. I work on the scientific strategy; I try to convince people at the highest level with good arguments... Politicians are not stupid people. They are very smart. Too many of my colleagues make the mistake of thinking them stupid."

I asked Zichichi what was the place of a scientist in Italian politics: "Nonexistent."

"But you have a lot of influence." "I am the exception not the rule."

"How do you do it?"

"I don't know how I do it. I think it's because they understand me and not the others."

And yet "I don't like to waste my time with politics. I took the presidency of INFN because I thought we were going to have troubles. The first thing I like to do is the research I am interested in. But you cannot spend your life complaining . . . some time ago I was arguing about strategy and so on with my colleagues in INFN, and at a certain point they said well, you cannot refuse to be president if you really want to go on like this. I would have preferred someone else to step in; but I realised I had to accept responsibility for the things I wanted to get done."

"Do you have any other administrative ambitions?"

"No. Zero. Absolutely no." I asked about CERN. "In CERN I do only physics. I've never had any responsibility of any kind. And I'm very glad, for there must be a place where you do only physics." Could CERN be better run? He was not in a position to say. "It is always easy to criticise organisations. I have a positive attitude to anything existing. But what I can tell you is that it is easy for big organisations to slip out of purely scientific control. I am facing this problem at INFN, and that is only one-tenth the size of CERN."

"Would you like to be director of CERN?"

"No. Because if you are director of CERN you cannot do any more physics. And I want to do physics. It is all right for a theorist. But if you are an experimenter you must make a choice: either you are director of CERN or you do physics. The games I am in now, I can combine with my research; I would feel without an important part of myself if I had to give up physics."

Erice perhaps weighs equally with research in Zichichi's constitution: "I am in touch by telephone for a few minutes every day." Why did he start the summer school? For a complex of reasons. "As you know Sicily is a place of great culture. Pretty well every culture but the Chinese has been through Sicily. But it is an underdeveloped part of Europe. I was not living there, and in a certain sense I felt guilty. But what could I do?"

"One thing was clear to me. The universities started 1,000 years ago because people wanted to know what was going on at the frontier or knowledge. Books were very slow. So people had to meet. But now universities cannot bring people to the frontier because of the great development of modern knowledge. So the old university spirit has been lost."

"People still want to be brought to the frontier. But who is going to teach you? It may be that at X you have the greatest world specialist in some discipline and you are lucky; but you miss the other disciplines. So if you can establish a place where people can be brought to the frontier of various fields then they will come. That is the principle of the Ettore Majorana Centre at Erice."

The school is financed by the Sicilian Government (Sicily is independent of Italy but for foreign policy), by INFN, and occasionally by other bodies such as NATO. When it started Zichichi had offers of buildings. "But underdeveloped countries are strewn with cathedrals in the desert. I wanted to be sure this place would work. And Erice beautiful, of human dimensions."

Erice, home of Zichichi's summer school.

Erice is built on a volcanic outcrop of rock, like a natural fortress. On one street you walk on the same stones as the Romans; more recently it was like a Switzerland in Sicily, housing and protecting the richest families. Zichichi's office is the highest part of Erice. "The view from there is absolutely fantastic." The 'summer' school (it lasts from March to December) is the whole economy of the town, and, according to one enthusiastic visitor the few inhabitants (some 100 or so, says Zichichi) bow their heads to Zichichi as he passes.

Zichichi hands out prizes to the best students (in fistfuls of Lire at the end of a course, an ex-student says) "but it is not easy to win a prize. The people who go there are really very brilliant. It is a pleasure to be there."

In March this year Zichichi 'emerged' as President of the European Physical Society, through a similar process to the one that found him president of the INFN: he wanted to do things. Following in the footsteps of his predecessor—and father-in-law—Gilberto Bernardini he has a romantic ideal for the EPS, uniting East and West and forging links among nations: "We should contribute to the cultural

unification of Europe."

Zichichi also sees the EPS as a source of "one of the greatest human feelings", friendship. "In the present age when there is an enormous amount of communication and we know what is going on on the other side of the world, we don't know our neighbours two metres away. And it is very important for physicists to talk, to get to know each other."

The EPS should also play a role in the five great physics projects in Europe: a giant proton synchrotron (probably in the USSR); a very large electron-positron colliding beam machine; JET; a large synchrotron radiation laboratory; and a millimetre wave radio interferometer. It should also develop proposals on the physics components of two new teaching institutions at present under discussion in Europe: a European 'science university' and a 'Mediterranean polytechnic' for the underdeveloped regions of the Mediterranean. And it should encourage the exchange of students and professors, perhaps for whole periods of a year's teaching: "imagine the impact of a London professor of quantum mechanics teaching in say Palermo, or Leningrad, for a whole year. Sabbaticals are not enough. We need to interest governments in this."

In the end Zichichi will always come back to his physics. He is an unconventional researcher. He was the first to look at the production of leptons in collisions of hadrons, work which eventually led to a Nobel Prize for Samuel Ting in the discovery of the 'hidden charm' particle J/ψ . "Ting mentioned me in his Nobel address as the pioneer. I can be proud and ashamed—proud that I started, and ashamed that I gave up". Also he spent five years searching for a lepton heavier than the muon at Frascati, by looking at electron annihilations producing an electron, a muon, and anything—the same reaction in which Martin Perl at Stanford discovered the 1.7 GeV tau lepton ten years later (the tau was just above the Frascati energy, like the J/ψ itself. There is little doubt that Frascati's energy was very unfortunately chosen.)

Now Zichichi is "trying to break the proton". The concept that the quarks are infinitely bound into the proton "is only at the level of 'theoretical feeling'" says Zichichi. "There is no proved theorem that says they should stay in there." Zichichi, while admiring elegant theory, has no truck with theoretical speculation, any more than he has time for reading the fantasies of novelists. In the matter of the proton he wants to ask Nature her logic. He has, as he puts it, "a very realistic view".

Cholera and related diarrhoeas ('turista')

from Richard A. Finkelstein and Mary Boesman-Finkelstein

CHOLERA and the related diarrhoeal diseases extract an incalculable global toll in human misery, morbidity and mortality. They also have a direct impact on human nutrition and growth and affect world food supplies through their effect on livestock. On August 6-11 they were the subject of the 43rd Nobel Symposium* at which 30 experts discussed the epidemiology, molecular biology, immunology, pathophysiology and significance of the enterotoxigenic enteropathies as a worldwide health problem. The symposium could not have been more timely; as a result of the tremendous progress during the past decade, there was a lot to be said.

Of the many highlights of the symposium, the dramatic advances in the treatment of cholera and related diarrhoeas, the dynamic interaction between diarrhoeal disease and malnutrition, developments in understanding the pathogenesis of diarrhoea at the molecular level, and the imminence of a living attenuated vaccine for cholera and the immunologically related enterotoxigenic enteropathies are certainly worthy of further brief review.

The remarkable developments in therapy of cholera and related diarrhoeal diseases pre-eminently illustrate the practical rewards of basic research. The results would certainly have been gratifying to the late Dr Robert Allan Phillips who, were he alive, would have been a key figure at this conference, as it was he who pioneered both intravenous and oral fluid and electrolyte therapy. His observation (Phillips *Fed. Proc.* 23, 705; 1964) that the incorporation of glucose in oral solutions might completely eliminate the requirement for intravenous fluids in the average cholera case was clearly substantiated in the symposium independently by L. Mata (Costa Rica), S. C. Pal (Calcutta), D. Barua (WHO, Geneva), W. B. Greenough, III (Dacca), T. Hendrix (Johns Hopkins), M. Field (Chicago), and M. Levine (Maryland). All but a small percentage of diarrhoeal patients can now be treated successfully solely

with orally administered electrolyte solutions. This can be accomplished, effectively and economically, by the distribution of packets containing preweighed amounts of glucose, NaCl, KCl and NaHCO₃ to be added to measured volumes of water in the hospital, in local treatment centres and, most importantly, in the home, even in the most rural and underdeveloped areas. In a small number of severe cases, particularly those with emesis precluding oral rehydration, intravenous fluid therapy is still required, but even some of these can be treated orally if the electrolyte solutions are administered in small but frequent increments. It is only a minor limitation that antibiotics, which have been shown to reduce the duration of bacterial shedding and of the diarrhoea, are not presently included. The impact that decentralisation of treatment might have on the ecology of the pathogens involved should be a subject of surveillance in the future. Other questions that remain to be answered are whether other energy sources can be substituted for glucose and whether different formulae are required for diarrhoea due to rotaviruses or other agents.

That certain antibiotics, administered prophylactically, can reduce the incidence of diarrhoea in travellers was established by B. Sack (Johns Hopkins University) in studies with Peace Corps volunteers. In this population, enterotoxigenic *Escherichia coli* are responsible for the majority of cases and, fortuitously at present, the majority of these strains are antibiotic sensitive. However, because of the spectres of drug resistance and alterations of normal flora leading to superinfection, participants at the conference agreed that prophylactic antibiotics, if used at all, should be restricted to short-term travellers at high risk.

The possibility of pharmacological intervention after the onset of diarrhoea was also raised and supported by experimental studies by Hendrix and I. Lönnroth (Göteborg). At the moment, two drugs, chlorpromazine and nicotinic acid, show promise in animal studies and merit further consideration for controlled study in man.

Contrary to popular belief, evidence presented by Mata indicates that rather

than malnutrition predisposing to infection, the reverse seems to be the rule—'malnutrition is determined by diarrhoea.' With newborn infants and children in particular, especially in developing areas, there is a tendency to withhold nutrients during diarrhoeal illness. Mata's studies in Central America, supported by observations of Barua, clearly indicate that when such children are adequately treated, by oral therapy, during their multiple bouts of diarrhoea, they grow better than their counterparts—the stunting which occurs during and following illness does not happen. This work has the important implication that availability of food is not the major problem in 'malnourished' children. Rather, the problem is to educate the people to provide proper treatment and normal (adequate) diet throughout periods of diarrhoeal disease. This is particularly important during the nursing period. Mata's message was also that we should be careful to differentiate between susceptibility and severity, recognising that the malnourished individuals are most frequently found in poor sanitary environments.

Epidemiologically, it was acknowledged that cholera declines when the water supply is freed of contamination with human faeces. It is not clear, however, that this is the case with other enterotoxigenic enteropathies such as *E. coli* diarrhoea, which seems to be transmitted primarily within the household and by food. The problems of developments in sanitation, which could solve the cholera problem, while recognised by the participants, were felt to be beyond the province of this conference.

Presentations by M. Gill (Harvard University) and M. Field (University of Chicago) revealed that for the second and third times (diphtheria being the first), the pathogenesis of infectious diseases is within a hair's breadth of being totally understood at the molecular level. Field, who inspired the recognition that cholera enterotoxin (choleragen) acts by activating host cell

*The symposium was held at the Nordic Education Centre, Stockholm, and was excellently organised by Orjan Ouchterlony, Jan Holmgren, John Craig and Dhanan Barua. Review papers provided the foundations for workshops culminating in recommendations for the future. The complete proceedings, workshop summaries and recommendations are to be published by S. Karger, AG, Basel, early in 1979.

Richard A. Finkelstein is Professor of Microbiology and Mary Boesman-Finkelstein is Faculty Associate in Biochemistry, University of Texas Southwestern Medical School at Dallas.

adenylate cyclase, presented new evidence that ST (the heat-stable low molecular weight enterotoxin(s) of *E. coli*, of which one example was characterised by D. Robertson (University of Kansas) as a peptide of 47 residues) acts by activating host cell (specifically intestinal epithelium) guanylate cyclase, while Gill indicated that the A-subunit of cholera toxin catalyses primarily the ADP-ribosylation of a GTP-binding protein which, according to observations by Z. Selinger, traps adenylate cyclase in its activated state. The subsequent events, catalysed by cyclic-AMP or cyclicGMP, which lead to the increased electrolyte and fluid secretion, are still a grey area.

S. Falkow (University of Washington, Seattle) dynamically demonstrated the application of the newly-developing recombinant DNA technology to the solution of problems of pathogenesis, with the object of creating useful new microbial strains, rather than new pathogens, with evidence for the cloning of the ST and LT (heat-labile cholera-related enterotoxin) genes of *E. coli*. He supported the observations of F. Ørskov (University of Copenhagen) that the *E. coli* strains which are selected to become enteropathogens (that is, which can effectively receive *tox* plasmids and other essential virulence factors) may be restricted to a relatively small number of serotypes which happen to be relatively good genetic recipients. Some 'non-toxigenic' strains of *E. coli* of proven pathogenicity for man in volunteer studies may produce toxins which are active in other than the usual models, according to Levine. Other essential attributes of virulence, such as chemotaxis and adhesiveness leading to colonisation, were discussed by R. Freter (Michigan). J. Craig (New York) pointed out that cholera vibrios differ in the amount of toxin they elaborate *in vitro* under two different conditions of cultivation. The advantages and limitations of available techniques of recognising enterotoxins and their antibodies were discussed by Ö. Ouchterlony, who also presented a novel simple method of assay based upon changes in hydrophilic character of antigen-antibody complexes on plastic surfaces. The essential roles of the host cell glycolipid receptors, the G_{M1} ganglioside, elucidated by the pioneering observations of W. E. van Heyningen, were reviewed and extended by L. Svennerholm and J. Holmgren (Göteborg).

The possibilities of immunological intervention were high among the priorities of the Symposium. J. Feeley (Atlanta) extensively reviewed the scientifically controlled field studies of cholera vaccines composed of killed vibrios administered parenterally, and concluded, in accord with previous

judgment, that the benefits derived did not justify the cost of vaccination. According to Barua, in consideration of these observations, requirements for cholera vaccination were removed from WHO regulations in 1973. Nevertheless there is the possibility of improvement, as brought out by more recent studies, presented by I. Joó (Hungary) and Pal, on alum-adsorbed bacterial vaccines which seem to generate greater protection in the susceptible infants and children of endemic areas than previously tested un-adsorbed vaccines. Although cholera toxoid administered parenterally offers no protection according to the field studies summarised by N. Ohtomo (Japan) and G. Curlin (Dacca), the synergistic protective effect observed experimentally with combinations of toxin antigen and somatic antigens in studies by A.-M. Svennerholm (Göteborg) is worth further consideration. She also indicated the potential value of assaying the antibody content of milk from immunised lactating women as a reflection of the local (intestinal) secretory antibody response. N. Pierce (Johns Hopkins University) reviewed extensively his observations on the kinetics of formation of antibody-containing cells in the lamina propria in response to a variety of combinations of orally and parenterally administered toxin antigens in experimental animal models and concluded that the nature of the antigen is important and that immunological suppression may result from some regimens. J. Holmgren (Göteborg) indicated that species differences may also be important, as illustrated by his studies in the orally immunised mouse model described earlier by Fujita and Finkelstein. J. Murphy (Harvard) reviewed genetic studies in his laboratory which have resulted so far in the isolation of two hypotoxinogenic mutants of strain 569B which produce reduced amounts of subunit A and little, if any, subunit B.

That solid immunity against cholera is indeed feasible has been established conclusively by studies in volunteers as summarised by Levine. Volunteers convalescent from induced cholera were found to be virtually completely refractory to subsequent challenge with cholera vibrios of either the homologous or heterologous serotype. Therefore it is clear that the disease itself is an immunising process, although the mechanism(s) and the nature of the immunising antigen(s)—somatic antigens, enterotoxin, colonisation factors, flagella, outer membrane proteins, or a combination—are not yet known. Immunity to rechallenge after induced *E. coli* diarrhoea was markedly less effective.

In an earlier session, R. A. Finkelstein (University of Texas, Dallas) sum-

marised the laboratory production and isolation of enterotoxins; elucidated criteria for defining enterotoxins and 'enterocytotoxins'; issued a caveat against the tendency to regard all newly described toxicities as toxins; and also reported the isolation with T. Honda, of a mutant of *Vibrio cholerae* which offers promise as a live vaccine against cholera and related diarrhoeas. Discussed further in the Immunology workshop, the mutant, called 'Texas Star', is avirulent in the sensitive infant rabbit model, has shown no signs of reversion, and seems to produce only the immunogenic B (binding) portion of the cholera enterotoxin. It is hoped that the mutant will be shown to be innocuous in volunteer studies and that it will simulate infection with virulent vibrios by producing solid immunity to cholera, and potentially to other diarrhoeas as well, by means of the common toxin B antigen. As a previous hypotoxinogenic mutant, M13, isolated in our laboratory, was harmless in volunteers and induced cholera immunity, this expectation may not be unrealistic.

In the immunology workshop it was emphasised that in volunteer studies, which are an effective step toward vaccine development, the highest internationally acceptable ethical standards must be followed with regard to selection, education, and respect for the rights of volunteers.

Participants were reminded of how far we have come in a short time by the presence of one of the Indian investigators, S. N. De (Calcutta), who in the late 1950s first showed that the symptoms of cholera could be produced in laboratory models by cell-free products of the cholera vibrio. □

Ultra-cold neutrons in superfluid helium

from P. V. E. McClintock

THE first measurements of the rate at which ultra-cold neutrons are produced within a vessel of liquid helium, reported in a recent issue of Physics Letters (66A, 469; 1978), strongly support the earlier suggestion by Golub and Pendlebury (Physics Letters 62A, 337; 1977) that it might be possible to fill a neutron bottle with trapped neutrons to an unprecedentedly high density if superfluid ⁴He were used as the internal medium. The production measurements were carried out in Grenoble at the Institut Laue-Langevin by P. Ageron and W. Mampe (ILL) in collaboration with R. Golub and J. M. Pendlebury (Sussex University).

Ultra-cold neutrons (UCN) are neu-

trons of such low energy that they are totally reflected from material surfaces at all angles of incidence, so that it becomes possible to confine them inside a suitably designed container (neutron bottle), where experiments can then be conducted in a relatively leisurely fashion—compared to neutron beam experiments where the time of observation is restricted to about 1/30 s at most—to elucidate their properties. If they could be trapped at sufficient density for periods comparable with their lifetime (neutrons decay by β -emission in about 15 minutes), then it might become possible to determine certain fundamental constants, such as the electric dipole moment of the neutron for which there are various theoretical predictions but, as yet, no positive measurements. The main difficulty is that the present technology available for UCN production, exploiting the very low energy Maxwellian tail of the thermal distribution of neutrons within a nuclear reactor, leads to trapped UCN densities of only about 1 cm^{-3} , which is not really adequate for the proposed experiments.

Golub and Pendlebury's suggestion amounted to a completely different technique by which UCN might be produced: by down-scattering in liquid helium of neutrons with an initial velocity of about 450 m s^{-1} . They pointed out that, when a neutron of this particular velocity travels through a bath of superfluid ^4He , there is a finite probability that it may spontaneously create a thermal excitation (in effect, a single quantum of sound) and, in doing so, lose almost all its initial energy. In its final state it will be an ultra-cold neutron, moving at less than 5 m s^{-1} , and unable to escape from the container. Their proposed UCN source consists, therefore, of a container of superfluid ^4He whose walls are transparent to neutrons with velocity of 450 m s^{-1} , placed in a beam containing a relatively large proportion of neutrons of this velocity. Most of the neutrons will pass straight through and out the other side, but a certain number will create excitations, enter the UCN region and become trapped.

The UCN density attainable by this method clearly depends on a balance between the production rate and the loss rate. Losses of UCN from the bottle will occur inevitably through β -decay but, in addition, can also arise as the result of up-scattering by thermal excitations (the converse of the production mechanism), absorption by impurities in the ^4He , or inelastic scattering from the walls. The latter phenomenon has restricted the storage times achieved in evacuated room-temperature bottles to about 30 s, but it is expected to become much less important at the temperatures over

1 K where the helium filled bottle will be operated. The most potent neutron absorber likely to be present in the liquid is the other isotope of helium, ^3He : it will be necessary to reduce the ^3He isotopic impurity content to a level about four or five orders of magnitude below that (a few parts in 10^7) found in ordinary commercial ^4He . Fortunately, however, purities even greater than this can quite readily be achieved using the heat-flush isotopic separation method recently developed at Lancaster, and neutron absorption within the body of the liquid is not therefore expected to be a problem. Neither should up-scattering processes since, provided the bottle is operated at a temperature below 1 K, the number of excitations with the appropriate energy to initiate such events will be quite negligible. The main unknown factor has been the production rate and, although Golub and Pendlebury did their best to estimate it, the calculation was by no means straightforward and it incorporated a number of assumptions which could have been in error. Hence the importance of the work now being reported from the ILL, which constitutes the first experimental measurement of the UCN production rate in superfluid helium.

The arrangement used was extremely simple. A vessel of liquid ^4He , whose temperature could be reduced by pumping, was placed in a horizontal neutron beam. Ordinary commercial ^4He was used, and so no provision was made for storing any UCN which might be produced. Instead, a neutron guide tube was provided to lead the UCN out of the liquid helium to an external neutron detector. The guide incorporated five right-angled bends to enable neutrons of higher energy to escape through its walls and thus to ensure that only the UCN could reach the detector and be counted.

In the event, the neutron counting rate increased rapidly to about 5 s^{-1} when the temperature of the liquid was reduced below its superfluid transition temperature at 2.2 K. When a 0.5 mm thick stainless steel plate, totally opaque to UCN but partially transparent to neutrons of higher energy, was placed so as to block the guide tube, the counting rate fell to the background level of 0.5 s^{-1} ; but it returned to its former value again as soon as the plate was removed. Some 24 hours later, as the last of the liquid helium boiled away, the rate fell once more to the background level. It seems virtually certain, therefore, that the detected neutrons were UCN produced in the liquid through the mechanism proposed by Golub and Pendlebury. Furthermore, the measured production rate was found to be in remarkably good

agreement with the value which they had calculated.

This is a very encouraging result. It implies that the fullscale neutron confinement cryostat now being planned at the ILL, which will incorporate a sample of isotopically ultra-pure liquid ^4He , is likely to store UCN at densities at least sixty times larger than have been attained by conventional methods—and perhaps a thousand times larger, if the problem of wall losses can be overcome. □

Progress in Fusion Research

from a Correspondent

TOKAMAK rules. That was the essential message from the 7th International Conference on Plasma Physics and Controlled Nuclear Fusion Research held at Innsbruck from 23–30 August last. The results from the large (PLT) tokamak at Princeton (USA) were presented and discussed in some detail. In particular the scientific basis for the widely publicised claim that a temperature of 60 million degrees had been reached was carefully examined and finally accepted. The discussions highlighted the difficulties of unambiguous measurement of ion temperatures in such plasmas. Indeed it can be argued that the obsession with 'temperature' is a hangover from the Zeta days and that in these plasmas, particularly those heated by powerful neutral beams, the single crucial number is the ratio Q of the energy released in fusion reactions to the energy input. In the Princeton experiment with 1.7 MW of neutral deuterium beam power into a deuterium plasma, a neutron emission of $4 \times 10^{12}\text{ neutrons s}^{-1}$ was measured; at $\sim 3\text{ MeV}$ per reaction, one can calculate that this corresponds to $\sim 20\text{ W}$ of fusion power and hence to $Q \sim 10^{-4}$. If a tritium beam had been used, then the more favourable cross-section and larger energy release would have increased Q to $\sim 5 \times 10^{-3}$. The new tokamak TFTR at present under construction at Princeton is designed to achieve $Q > 1$ through the reduction in diffusive losses by the use of larger dimensions. In the light of the new results its chances of success look good. For a power reactor $Q \sim 20$ would be needed.

Results from other tokamak experiments around the world showed an increasing ability to reduce the contamination of the plasma by impurities. With cleaner plasmas it is possible to reach higher densities than before and to increase the ratio of toroidal plasma current to toroidal magnetic field. Thus

in the Alcator experiment a record value of the product of plasma density and containment time was reached, ie. $\langle n\tau \rangle = 3 \times 10^{13} \text{ cm}^{-3} \text{ s}$. The plasma here was relatively cold with a temperature of ~ 8 million degrees.

Despite the success of tokamaks in confining hot plasma the difficulties of developing the concept into a practical power producing reactor are immense. One major problem is the relatively low ratio β between the plasma pressure and that of the magnetic field. The plasma produces the power while the magnetic field costs money. Thus many studies have suggested that the minimum acceptable β for a reactor is 5–10%. In present tokamaks β is typically less than 1%. Theoretical work from Culham, Lausanne and Princeton presented at the conference suggests that the maximum β in a tokamak consistent with plasma stability is only about 3%. This leaves an awkward gap and it is therefore of crucial importance to carry out definitive experiments to test the theory.

The fact that the road to the tokamak reactor is clearly a very difficult one encourages the continuation of work on other magnetic confinement approaches where the difficulties are equally daunting but different.

Thus work continues on a variety of magnetic confinement schemes including the stellarator, reversed field pinch and mirror machine. Steady progress on these lines was reported at Innsbruck but no startling breakthrough of the kind that would lead to any switch of emphasis away from the tokamak. A dark horse in the competition is the Elmo Bumpy Torus (EBT) experiment at Oak Ridge. In this experiment a steady state toroidal plasma is produced by high power (60 kW) microwave heating with an ion temperature of about 2 million degrees. The practicability of this approach has recently been greatly increased by technical developments in the generation of high power millimetre microwaves. A reactor design based on the EBT principle was presented at Innsbruck. A microwave power of the order of 100 MW at $\sim 100 \text{ GHz}$ is envisaged.

The major alternative to magnetic confinement is the inertial approach in which a tiny pellet is compressed to densities of $\sim 10^{25} \text{ particles cm}^{-3}$, heated to thermonuclear temperatures and holds together under inertial forces for long enough (10^{-11} s) to give an adequate yield of fusion energy. Presentations on this subject at Innsbruck were relatively muted, the major groups being mainly pre-occupied with getting the necessary multi-terrawatt driver systems (lasers, ion beams and electron beams) to work. Thus the essential

feature of compression to very high densities has yet to be experimentally demonstrated. Most existing experiments are done with so called exploding pusher targets. In these high pressure (100 atm) deuterium and tritium gas is compressed by the explosion of the surrounding glass microsphere. Experiments of this type around the world with CO_2 and Nd glass lasers (including one at the Rutherford Laboratory), have produced a great deal of information, diagnostic experience and Q values of $\sim 10^{-3}$. Experiments aimed at $Q \sim 1$ using the Shiva laser at the Lawrence Livermore Laboratory (Nd glass, 26 TW) and the Antares laser at Los

Alamos (CO_2 , 100 TW) are due to begin soon. The problems of converting these inertial confinement systems into fusion reactors with the necessary high repetition rate and adequate containment of the successive small explosions are very great. The Livermore group propose to surround the exploding targets with a 100 ton, 1 m thick falling curtain of liquid lithium to absorb the neutrons and reduce radiation damage to the external structure.

Certainly all the concepts presented at Innsbruck lead to very complex and difficult reactors. The assessment and mastery of this complexity will be one of the major tasks for the coming years. $\square$

Zr₃Al creeps in a petty pace

from Robert W. Cahn

In 1956, A. H. Cottrell predicted that metallic uranium, while undergoing steady fission, would lose most of its resistance to creep under stress, and he initiated a very simple experiment with a loaded uranium spring inside a reactor. His hypothesis of enhanced irradiation-creep was promptly confirmed and this had immediate consequences for the design of the British nuclear reactors of that time.

Cottrell's crucial hunch has been followed up in the intervening years by a large body of experiment and theory. Not only a fuel but also its container is subject to this form of creep, and it is a matter of special concern when a 'cladding material' is weakened, for the container has the function of retaining fission products both solid and gaseous; the latter exert a pressure which must be resisted by the container. After much experiment as well as very sophisticated theoretical physics during the past few years, the mechanisms both of irradiation-creep and of the related process of void-swelling (when minute cavities form in the container during reactor service) are now understood in outline. Neutron irradiation produces equal numbers of vacancies and interstitials, some of which recombine quickly; the rest migrate to and become absorbed at 'sinks', of which dislocations are the most important. The crucial point is that a dislocation is a 'biased sink'—that is to say, it has a slightly greater tendency to absorb interstitials than vacancies (the bias is typically around 2%); this bias is explicable in terms of differing elastic interactions of the dislocation with the two types of point defect. The excess of vacancies so generated eventually condenses to form the minute aggregates called voids (whose existence was first reported in *Nature* in 1966). Furthermore, an external stress can increase the bias and thus

accelerate the climb of dislocations which must result from a net flux of interstitials to dislocations. That accelerated climb in turn is apt to produce accelerated creep under the action of the external stress, since under certain circumstances, the climb rate is rate-determining for creep.

The recognition of the central importance of point defect kinetics in irradiated alloys has opened the way for a new kind of alloy design—the attempt to predict what kind of alloy might be least susceptible to enhanced creep and void-swelling. The matter is of special interest in fast reactors and in water reactors; the latter all use container materials based on metallic zirconium, which combines an appropriately low neutron capture cross section with good corrosion resistance in hot water under irradiation. A determined attempt is now under way in Canada to improve on the 'zircalloys' in current use, and the project is based on a most ingenious hypothesis—the postulated influence of atomic order in an alloy, Zr_3Al , in reducing the net flux of interstitials to dislocations and, thus, in reducing liability to irradiation-creep.

It is well established from comparative studies of successful and unsuccessful industrial innovations that the most important single factor in ensuring success is a resolute and energetic 'product champion'. The champion of Zr_3Al is E. M. Schulson, a metallurgist on the staff of Chalk River Nuclear Laboratories in Canada. He argued in 1972 that this alloy had the virtues of low neutron absorption and promising mechanical properties, and further suggested that irradiation-creep might be reduced. The basic postulate here is that ordering generally reduces the rate of vacancy migration in an alloy (there is an often cited study of beta-brass, in 1956, which first estab-

lished this point); at any given temperature, a slowing down of vacancy migration gives more time for recombination of vacancies and interstitials and this reduces the net flow of interstitials to biased sinks, and thereby reduces irradiation-creep rate under a given stress. In pursuit of this hypothesis, Schulson has orchestrated a large range of studies, most of which have come to publication during the past 1½ years: it now looks as though his ingenious hypothesis is justified, though a full study of the irradiation-creep itself is yet to appear.

The hypothesis itself is outlined in a paper by Schulson in *J. Nucl. Mat.* **66**, 322; 1977. Here he also reports that stress-relaxation of Zr_3Al under neutron or 1 MeV electron irradiation at 570 K (a realistic reactor temperature) is a factor of three or more lower than that for any zirconium-based alloy studied to date. This striking experiment is to be fully described in a conference report to be published by ASTM. Zr_3Al is ordered (Cu_3Au type, $L1_2$) up to its peritectoid transformation at 1,265 K, but can be progressively disordered by radiation damage. Several studies have sought to establish whether, at temperatures of practical interest, radiation-disordering goes far enough to nullify the advantage which forms the basis of Schulson's hypothesis. This is a matter of balance between radiation damage and spontaneous reordering, and this balance depends on the rate of damage and the temperature. Accelerated damage by ion bombardment (Howe & Rainville *J. Nucl. Mat.* **68**, 215; 1977) or 1 MeV electron bombardment (Carpenter & Schulson *J. Nucl. Mat.* **73**, 180; 1978) showed that at realistic service temperatures, large doses leading to several displacements per atom were required to produce substantial disorder above 575 K. Neutron bombardment in reactors would produce less damage and therefore less disorder than either ions or 1 MeV electrons. Further studies (Rosinger *J. Nucl. Mat.* **66**, 193; 1977; Schulson, *Acta Met.* **26**, 1189; 1978) have established that neutron irradiation strengthens Zr_3Al at all temperatures, and another (Schulson & Roy *J. Nucl. Mat.* **71**, 124; 1977) has elicited the remarkable fact that irradiation actually reduces the notch-sensitivity of the alloy (which is in any case not severe) and, at room temperature, the notched tensile strength is even enhanced by irradiation. This behaviour is quite at variance with the normal effect of irradiation on notch-brittleness, which is pronounced, for instance, in ferritic steels. Another study (Schulson *Met. Trans.* **9A**, 527; 1978) established that the fracture morphology of Zr_3Al indicates a ductile fracture mechanism.

These various experimental studies have now been supplemented by a thorough theoretical investigation of the kinetics of point defect annihilation and irradiation creep for a number of idealised imaginary alloys with various types of atomic order (Schulson, Swanson & MacEwen *Phil. Mag.* **A37**, 575; 1978). This very thorough analysis is based on certain assumptions about the change of migration energy for vacancies as a result of ordering and the further assumption that sink strengths are not affected by ordering. Numerical results are obtained for vacancy concentration as a function of temperature, for net interstitial flux to dislocations for various assumed vacancy migration energies and, finally, for the factor of reduction of dislocation climb rate due to ordering. In the temperature range of interest, for the

idealised $L1_2$ alloy, the climb rate (and therefore the irradiation-creep rate) is shown to be reduced by 30–70%, depending on dislocation density and whether simple or super-dislocations are present. This paper marks a milestone in the application of exact atomistic theory to the prediction of irradiation behaviour.

Zr_3Al may turn out to behave even better than theory indicates, because preliminary electron microscopy indicates that the alloy, after irradiation, has a smaller than normal density of dislocation loops. Some unidentified healing mechanism, it seems, may render the alloy even less liable to the processes that enhance irradiation-creep than is predicted by theory.

Robert W. Cahn is Professor of Materials Science in the University of Sussex.

Unfolding Troponin-C

from Jonathan Seymour

TROPONIN-C (TN-C) is one of the most interesting proteins in muscle, because it lies at the kernel of the mechanism for controlling contraction and relaxation. When the concentration of Ca^{2+} around the thick and thin filaments of muscle is high, TN-C binds Ca^{2+} and contraction takes place. In contrast, when the Ca^{2+} concentration is low, TN-C loses its bound Ca^{2+} and contraction is inhibited and the muscle relaxes. This inhibition of contraction is produced by tropomyosin and the troponin complex, both of which are situated on the muscle thin filaments. The troponin complex consists of three components: TN-I, which exerts the inhibitory action; TN-T, which binds the complex to tropomyosin and TN-C, which is responsible for binding Ca^{2+} . Recent experiments have revealed how the structure and functions of TN-C are related.

TN-C has two binding sites which can bind either Ca^{2+} or Mg^{2+} . At low concentrations of Mg^{2+} , these Ca^{2+} - Mg^{2+} sites show a high affinity for Ca^{2+} . Also TN-C has two further sites that can bind Ca^{2+} only. These Ca^{2+} -specific sites show a lower affinity for Ca^{2+} than the Ca^{2+} - Mg^{2+} sites, in the absence of Mg^{2+} . The application of such techniques as proton magnetic resonance, circular dichroism and a measurement of tyrosine fluorescence have revealed the effects of Ca^{2+} binding at the different sites of TN-C. When Ca^{2+} binds to the Ca^{2+} - Mg^{2+} sites, the backbone of the polypeptide chain refolds, generating new lengths of α -helix. This large re-organisation of the molecule results in TN-C adopting a more stable conformation. Similar, but not identical, changes occur when Mg^{2+} is bound to the Ca^{2+} - Mg^{2+} sites. Further binding of Ca^{2+} at the Ca^{2+} -

specific sites results in smaller changes occurring, but there is some evidence for an accompanying increase in α -helix.

The primary sequence of TN-C reveals four regions (I to IV) of the polypeptide chain that are homologous with the Ca^{2+} binding sites of parvalbumin. Parvalbumin is a Ca^{2+} binding protein whose three dimensional structure has been solved, to an atomic resolution, by X-ray crystallography. These Ca^{2+} binding sites consist of a bend in the polypeptide chain, rich in acidic side chains, and flanked on both sides by α -helical regions. The immediate question arises, which regions of the sequence (I to IV) correspond to Ca^{2+} - Mg^{2+} sites and which to Ca^{2+} -specific sites? Detailed analyses of the sequences in the four regions led to contradictory results. Further progress was made by attaching probes to one cysteine residue in region III of the molecule. Using fluorescence measurements and E. S. R. techniques, it was established by Potter *et al.* (*J. of Biol. Chem.*, **251**, 7551; 1976) that region III corresponded to a Ca^{2+} - Mg^{2+} site.

Recently, the nature of all four regions has been unambiguously resolved by studying the Ca^{2+} binding properties of fragments of TN-C. Leavis *et al.* (*J. of Biol. Chem.*, **253**, 5452; 1978) used trypsin, thrombin and cyanogen bromide to cleave TN-C at different points along its polypeptide chain. The resulting fragments contained one or more of the four binding regions (I to IV). It was shown that regions III and IV corresponded to the Ca^{2+} - Mg^{2+} high affinity sites, in agreement with the earlier assignment of region III. It follows immediately that regions I and II correspond to the Ca^{2+} -specific sites. In addition two regions

of TN-C were identified that bound to TN-I. This is in agreement with similar work done on TN-C fragments by Weeks and Perry (*Biochem. J.*, 173, 449; 1978) and also with earlier work done on TN-I.

At the same time the work of Leavis *et al.* revealed a limitation of looking at fragments of TN-C. It was found that fragments containing the two Ca^{2+} - Mg^{2+} sites, regions III and IV, had a strong affinity for Ca^{2+} and could also bind Mg^{2+} . Further, cleaving the polypeptide, so that regions III and IV were on separate fragments, resulted in the isolated Ca^{2+} - Mg^{2+} binding sites changing their characteristics. Now they could only bind Ca^{2+} weakly and failed to bind any Mg^{2+} at all. This illustrates the importance of tertiary structure (relationships between different regions of the same molecule) for defining the properties of the binding sites. Indeed, the Ca^{2+} -binding properties of TN-C are related to its quaternary structure (relations to surrounding protein molecules), because when TN-C binds to TN-I, its affinity for Ca^{2+} increases by an order of magnitude.

In order to obtain a better understanding of how Ca^{2+} binding to TN-C releases the inhibitory effect of the troponin complex and tropomyosin, it is crucial to know which Ca^{2+} binding sites on TN-C are the regulatory ones. The bulk of the evidence suggests that it is the Ca^{2+} -specific sites that regulate contraction. Work with myofibril preparations indicate that the Ca^{2+} concentration at which their ATPase rate is activated is independent of the concentration of Mg^{2+} . Hence, only the Ca^{2+} -specific sites are involved in regulation; but work on the tension development in muscle suggests that raising the concentration of Mg^{2+} increases the Ca^{2+} concentration required for the muscle to be activated. This possibly implicates the Ca^{2+} - Mg^{2+} sites in regulation.

The solution of this dilemma would be an important advance in understanding how TN-C regulates contraction. A crucial piece of data relevant to this question is the concentration of Mg^{2+} in muscle. This is not accurately known, but it is believed to be in the range 0.1 to 5 mM. This knowledge would enable the metal ions bound to TN-C to be identified in contracting and relaxed muscle. When the Ca^{2+} concentration is high and the muscle is contracting, all four sites on TN-C bind Ca^{2+} . However in relaxed muscle when the Ca^{2+} concentration is low, the Ca^{2+} -specific sites are free of Ca^{2+} , while the Ca^{2+} - Mg^{2+} sites could be binding Ca^{2+} or Mg^{2+} , depending upon the concentration of Mg^{2+} . There is also much more to learn about the relationships between TN-C and its

neighbours TN-I and TN-T. For it is these changing relationships, as TN-C binds and releases Ca^{2+} , that release and trigger the inhibitory action of troponin and tropomyosin.

Jonathan Seymour is at the M.R.C. Cell Biophysics Unit, King's College, London.

Nuclear resonance & synchrotron radiation

from G. V. Marr

THE electromagnetic radiation (synchrotron radiation) emitted by high energy electrons when they are constrained by magnetic fields to move in circular orbits in an electron synchrotron or storage ring is now well known and much used as an intense source of ultraviolet and X-ray photons. Because the electrons are injected as localised bunches into the synchrotron and are accelerated to speeds approaching the speed of light, the synchrotron radiation emitted is highly polarised and concentrated into tightly collimated beams forward-directed along tangents to the instantaneous electron orbit. The radiation emitted is characterised by the electron energy and the bending radius of the orbit so that its spatial and energy distribution is calculable. It appears as a continuum of radiation extending from the infra-red to the X-ray region with a peak in the XUV or X-ray region. It also possesses a pulsed-time structure determined by the orbiting frequency of the electron bunches. There are now more than 20 laboratories throughout the world, 7 of which are in Western Europe, where facilities exist for the exploitation of synchrotron radiation and research programmes are in operation to study problems in atomic, molecular, surface and solid state physics, in chemistry, and in the structural properties of solids and biological samples. In addition, X-ray microscopy, lithography, the calibration of light sources and detectors, etc., are applications of synchrotron radiation.

New applications are continuously appearing and an interesting extension of these activities to the observation of nuclear resonance excitation has been reported by R. L. Cohen *et al.* (*Phys. Rev. Letters* 41, 381; 1978). The interest is not so much that new data on the nucleus has been revealed, indeed the observations are of the well known 14 keV level of ^{57}Fe , but that the apparatus developed enables the resonance to be detected by the observation of a weak flux of conversion electrons emitted by the decay of the nuclear state in the presence of a much more intense electron flux from non-

nuclear electronic processes.

The method makes use of the fact that the University of Stanford storage ring can provide pulses of synchrotron radiation 0.3 ns wide every 780 ns. With a long lifetime (100 ns) against decay of the nuclear level it has been possible to gate the detector system so as to collect data 100 ns following the incidence of the synchrotron radiation pulses, thereby allowing photoelectrons, Compton electrons and long lived secondary electrons to dissipate before the detector is activated.

The synchrotron radiation was dispersed by a crystal X-ray monochromator to provide a band width of 3 eV photon energy centred about the 14 keV excitation energy. This radiation fell onto a ^{57}Fe enriched iron foil and the emitted electrons entered a continuous semi-conducting dynode electron multiplier which was divided into two stages with a gated grid between the two sections. The grid was gated "off" during the prompt photoelectron pulse and so removed the main cause of afterpulsing electrons which would be otherwise indistinguishable from the nuclear conversion electrons. Very low energy electrons having flight times of as long as 100 ns were removed at the electron multiplier entrance.

Under these conditions, the crystal monochromator was scanned over the energy of the ^{57}Fe nuclear resonance and the counting rate plotted as a function of X-ray energy. The width of the resonance is negligible (5×10^{-7} eV) compared with the band width of the monochromator so that the scan actually profiled the transmission function of the monochromator and the width and shape of the response reflect the monochromator output. Nevertheless the resonance was observed to occur at exactly the anticipated energy and was of the correct intensity. The authors also point out that their detector system can be used with advantage to provide a study of the Bragg-scattering profile of crystal monochromators in synchrotron radiation beam lines, thus allowing maladjustment of the monochromator or defining slits to be corrected *in situ*.

New synchrotron radiation sources are being designed specifically to make use of the synchrotron radiation rather than to provide high energy particles. In particular, the new 2 GeV storage ring under construction at the Daresbury Laboratory in the U.K. will be used to study the time structure of the radiation. Looking further ahead, the European Science Foundation is currently considering the design requirements for a European Synchrotron Radiation Facility for the 1980s.

review article

Fibronectins—adhesive glycoproteins of cell surface and blood

Kenneth M. Yamada & Kenneth Olden*

A recently characterised class of adhesive, high molecular weight glycoproteins is present on the surfaces of cells, in connective tissue matrices, and in extracellular fluids. These proteins may have important roles in cellular adhesion, malignant transformation, reticuloendothelial system function, and embryonic differentiation.

RECENT attempts to unravel the molecular mechanisms of cellular adhesion, malignancy, hemostasis, host defense by the reticuloendothelial system, and connective tissue structure have implicated glycoproteins with subunit molecular weights of 200,000–250,000. These proteins are now thought to be closely related, and are termed fibronectins (from the Latin *fibra*, fibre, and *nectere*, to bind, tie)¹. We shall review the discovery, structure, and possible biological roles of these glycoproteins (for related reviews, see refs 2–6).

Discovery and nomenclature

In 1948, Morrison *et al.*⁷ isolated a partially purified fraction of human plasma which they termed 'cold-insoluble globulin'. Other workers independently described the various proteins or factors listed in Table 1, which were named according to sources or biological activities (Table 2). Recent evidence indicates that all of these proteins are closely related, and that they are probably only one or two specific proteins—cell surface (cellular) fibronectin, and plasma fibronectin. Cell surface fibronectin is a major constituent of the cell surface of many cultured cells, and was discovered when cell surface proteins or carbohydrates were labelled radioisotopically or immunologically (Tables 1 and 3). This glycoprotein is also known as LETS protein¹⁹ or CSP²⁰, and has an apparent subunit molecular weight of between 200,000 and 250,000 by SDS-polyacrylamide gel electrophoresis^{2–6}. Plasma fibronectin is a dimeric glycoprotein with subunit polypeptides of 200,000–220,000 that circulates in vertebrate blood^{7,23–26}. Although also known as cold-insoluble globulin, purified plasma fibronectin is relatively soluble in the cold unless it is complexed with fibrin and fibrinogen^{7,23–25,27,28}.

Antisera raised against the plasma or cell surface forms of fibronectin readily cross-react, and antibodies specific for only one form have not yet been described^{13,27,29–31}. Monospecific anti-fibronectin antisera against either form specifically immunoprecipitate only fibronectin from cell homogenates^{32–34}. Current information summarised below suggests that although the two forms of fibronectin are very similar, they are probably not identical. Whether they are products of different genes, or of one gene and are modified post-transcriptionally, is not yet known.

Quantities and location

Cell surface fibronectin constitutes 1–3% of total cellular protein of embryonic or adult fibroblasts cultured *in vitro*³⁵. A few

permanent cell lines also display large amounts of fibronectin, but many other permanent fibroblastic lines have much smaller quantities that are detectable only by cell-surface labelling techniques³⁵. Cell surface fibronectin has also been found on astroglial cells³⁰ and on certain cultured epithelial cells^{36,37}, including blood vessel endothelial cells^{38,39,114}.

Cell surface fibronectin is located in striking fibrillar arrays on the surface of many cultured cells, as determined by immunolocalisation studies with anti-fibronectin antibodies (Fig. 1)^{3,6,29,30,32–46}. Cell surface fibronectin extends between cells, and is also found between cells and the tissue culture substratum^{3,29,32–34}. This localisation is consistent with a role in cell–cell and cell–substratum adhesiveness. In densely confluent cultures, cellular fibronectin forms a complex, interconnected extracellular matrix that may contain collagen or elastin^{3,10,12,29,32–46}. Electron microscopic localisation studies confirm that most of the fibronectin is present in extracellular fibrils and aggregates, with only small amounts present diffusely distributed along the outer surface of the plasma membrane of cells^{37,43–45,47}. Most cellular fibronectin can be detached and separated from plasma membranes centrifuged in sucrose gradients^{48,49}, and as much as half can be released from living cells incubated in 1M urea^{50,51}. Most of the protein therefore seems to be loosely associated with the membrane. In addition,

Fig. 1 Cell surface fibronectin on chick fibroblasts *in vitro*. A confluent culture was fixed and stained with affinity purified anti-fibronectin followed by fluorescein-labelled anti-immunoglobulin. $\times 520$.

*Laboratory of Molecular Biology, National Cancer Institute, Bethesda, Maryland 20014.

large amounts of cellular fibronectin are also continuously secreted or sloughed from cells into culture media^{10,20,30,37,53-58}

Fluorescently labelled antibodies have also been used to determine the locations of the fibronectins in embryonic and adult tissues. Fibronectin is present as extracellular fibrils in connective tissue, in primitive mesenchyme, and in many basement membranes^{59,60}. During embryonic development, fibronectin is first detectable on the cells of the blastula inner cell mass⁶¹. Later in development, fibronectin is lost as mesenchymal cells differentiate into muscle, cartilage, and renal tubular epithelium^{59,62}. It is not present in hepatocytes^{59,60}, in contrast to many other plasma proteins. Fibronectin is also present in amniotic and cerebrospinal fluids^{37,63,64}, and on platelets²³. Since anti-cell surface and anti-plasma fibronectins cross-react, it is important to note that most of these immunological studies do not indicate whether the fibronectins at each of these sites are the cellular or plasma form.

Plasma fibronectin (cold-insoluble globulin) is present in human plasma at 0.3 mg ml⁻¹ (ref. 23). As it binds to fibrin, its concentrations are lower in serum²³. Plasma fibronectin also binds to heparin, and together with fibrinogen will also form a cryoprecipitate⁶⁵. Plasma fibronectin can be covalently cross-linked to fibrinogen or to itself by plasma transglutaminase (activated factor XIII)^{25,26}. Factor XIII can also covalently crosslink cellular fibronectin to itself^{66,67}.

Concentrations of fibronectin in blood are decreased after extensive trauma, in the disseminated intravascular coagulation syndrome, and after reticuloendothelial system blockade following injection of colloids in animals⁶⁸⁻⁷². Levels of the protein are often elevated in cirrhosis and the cholestasis of pregnancy, possibly because of defective hepatic removal⁷³.

Decrease after malignant transformation

A major source of interest in fibronectin is the finding that the amount of cell surface fibronectin is usually decreased after cell lines are transformed by oncogenic viruses or carcinogens, and on cultured tumour cells (Table 3). However, there are exceptions to this generalisation, particularly among spontaneously transformed cell lines (Table 3).

The tumorigenicity (capacity to form benign or malignant tumours after injection into immunosuppressed or immune-compatible animals) of cell lines generally correlates with decreases in cell surface fibronectin^{29,45,99,100}, although a recent study of closely related transformed cells grown in semi-solid medium has cast doubt on this relationship (P. H. Gallimore, J. K. McDougall, and L. B. Chen, personal communication; see also ref. 95). Instead, decreases in this protein may correlate more with the propensity of cells to metastasise⁴⁵.

The decreases in cell-associated fibronectin after malignant transformation are 5- to 7-fold in chick fibroblasts and more than 10-fold in human fibroblasts and glial cells^{30,52,55}. However,

Fig. 2 Current model of fibronectin structure. Note elongated shape and distribution of inter-subunit disulphide bonds, adjacent sites that are highly sensitive to the proteases plasmin and trypsin, and the blocked amino termini. The oligosaccharides consist of a core of N-acetylglucosamine and mannose linked to asparagine residues with distal galactose residues that may be linked to terminal sialic acid or fucose residues.

decreases of more than 10-fold in cell surface fibronectin also accompany the establishment of several permanent rodent cell lines and these decreases are not accompanied by the acquisition of tumorigenicity³⁵. The potent tumour promoter phorbol myristate acetate also causes a reversible loss of fibronectin¹⁰¹.

It is obviously important to resolve whether there is any direct causal relationship between decreases below specific quantities of cell surface fibronectin and the propensity of cells to form tumours or to metastasise.

Functions of the fibronectins in adhesion

Fibronectins are thought to be involved in a wide variety of cellular activities (Table 2). The simplest unifying interpretation of these findings is that the fibronectins function as adhesive proteins that bind cells to other cells or to substrata (Fig. 3). This conclusion is based on experiments *in vitro* utilising model systems of cellular adhesion, in which purified fibronectin is found to increase the adhesion of cells to cells or to the substrata on which they are grown.

The first evidence suggesting that cellular fibronectin may play a part in cell-cell adhesiveness was the finding that fibronectin purified from cell surfaces behaves like a lectin and readily agglutinates fixed sheep erythrocytes in concentrations as low as 1 µg protein per ml (refs 50, 58). Purified cellular fibronectin binds directly to fixed erythrocytes and can be recovered intact⁵⁰. Proteases and chelating agents destroy the agglutinin activity; these agents are known to disrupt cell-cell adhesion⁵⁰. Purified cell surface fibronectin can also increase the aggregation of living dissociated chick embryo and baby hamster kidney (BHK) cells¹⁰².

Purified cell surface fibronectin can also mediate the attachment of dissociated cells to collagen^{17,102}. Treatment with cellular fibronectin also increases the extent or attachment or the resistance to detachment of several transformed cell lines to plastic tissue culture substrata^{56,103,104} (see also ref. 105).

Serum factors are required for the attachment of certain cells to collagen-coated dishes^{16,17,106,107}, or for cells to attach and spread on tissue culture dishes¹⁰⁸⁻¹¹¹. These cell attachment and cell spreading factors are now thought to be serum fibronectin (cold insoluble globulin)¹¹¹⁻¹¹³. Such serum factors can bind directly to collagen or tissue culture dishes in the absence of cells^{16,17,106,108-110}. The fibronectin-mediated attachment of cells to collagen or spreading on to plastic substrata requires divalent cations such as calcium and the expenditure of cellular metabolic energy^{16-18,106,108}. Certain cells with high levels of cell surface fibronectin do not require serum fibronectin for spreading⁵. These cells may use cell surface fibronectin, since cellular fibronectin is equally active in promoting cell spreading and attachment to collagen¹⁷².

Both plasma and cell surface fibronectins can be purified by affinity chromatography on columns to which denatured collagen has been covalently coupled^{102,107,115-117,123}. Denatured collagens types I, II, and III are substantially more effective in binding plasma fibronectin than native collagens^{116,117}. The specific sites of interaction of plasma fibronectin with denatured collagen consist of a strong binding site at residues 643-819 of

the collagen $\alpha 1$ chain, plus several other weaker sites^{117,118}. Type III is the most effective native collagen in binding plasma fibronectin^{116,117}. The physiological significance of these differences in binding is not yet known.

Plasma fibronectin may play an important part in the removal of collagenous and other debris from blood after injury via the sessile macrophages of the reticuloendothelial system. An extensive series of experiments had identified an 'opsonic protein' in plasma that was involved in reticuloendothelial system clearance of injected gelatin-coated colloidal particles from blood^{11,69-71,119-121}. Other independent studies had identified an 'anti-gelatin factor' in serum that would bind to gelatin, and that was required for macrophage ingestion of denatured collagen^{8,122,123}. Both the opsonic protein and anti-gelatin factor have been purified recently, and both seem to be identical to plasma fibronectin (cold-insoluble globulin)¹²⁴⁻¹²⁶.

Are all of these biological activities of the fibronectins shared by plasma and cell surface forms? Recent experiments suggest that although both proteins are equally active in promoting cell spreading¹¹³ and attachment to collagen, cellular fibronectin is more effective in haemagglutination and in restoring adhesiveness and normal morphology to transformed fibroblasts (see below). Nevertheless, it is clear that both fibronectins display adhesivity.

Reconstitution and inactivation experiments

A potentially more general approach to determining the functions of the cell surface form of fibronectin is to reconstitute it experimentally on the surface of cells missing this protein, that is, on to transformed cells. These experiments can help to identify which of the alterations in cell morphology or behaviour occurring after cells are transformed could be due to the loss of this protein.

In 14 transformed fibroblastic cell lines examined to date, purified cellular fibronectin partially restores a more normal fibroblastic appearance to the cells^{44,56,102,103,127}. The effects include restoration of the flattened cell shape, elongated processes, smooth cell surface, and prominent intracellular bundles of microfilaments containing actin and myosin that are characteristic of normal fibroblasts *in vitro*^{44,56,102-104,127}. In these experiments, amounts of cell surface fibronectin equal to those present on freshly explanted fibroblasts can be restored to the transformed cells¹⁰³, although the reconstituted fibronectin may not bind as efficiently as originally¹⁰⁷. The reconstituted fibronectin seems to be present in normal sites as evaluated by immunofluorescence^{34,56} and by its capacity to undergo normal antibody-induced redistribution after incubation with u-fibronectin antibodies³⁴ (see below).

Asterisks indicate activity known to be shared by both plasma and cellular fibronectins.

Fig. 3 Suggested relationship of cellular fibronectin to several biological activities (see refs 3, 102, 171 for discussion of evidence for this hypothetical scheme). The central activity of fibronectin would be to increase cell-cell and cell-substratum adhesion.

Besides affecting morphology, fibronectin treatment can restore a more normal social behaviour *in vitro*. For example, transformed fibroblastic cells tend to grow in relatively random patterns with cell bodies criss-crossing over one another, whereas normal fibroblasts tend to align in parallel arrays of cells. Fibronectin-reconstituted transformed cells show a restoration of this social alignment in approximately half of the cell lines tested^{56,102,103}. This defect in social behaviour is a common characteristic of cells transformed by oncogenic viruses and may result from a decrease in cell adhesion or to changes in specific cell recognition events such as contact inhibition of movement¹²⁸⁻¹³⁰. Another factor involved in maintaining cell alignment is released from cells by 0.2 M urea treatment¹³¹; however, this factor and fibronectin are clearly different molecules^{20,173}.

Fibronectin-treated cells also migrate more rapidly, both as single cells or as masses of cells migrating out from cell aggregates^{102,132,133}. These effects could be the result of establishing more effective cell-to-substratum traction¹³², or of a more asymmetric cell shape that promotes directed cell movements^{35,56,103,133}.

A complementary approach to investigating the biological activity of fibronectin is to incapacitate it with proteases or anti-fibronectin antibodies. Treatment of chick fibroblasts with purified antibody results in a rapid alteration in cell shape to a rounded morphology resembling that of many transformed cells that are deficient in cellular fibronectin³⁴. Cells treated with proteases that do not remove fibronectin tend to aggregate, whereas its removal results in cell retraction without such aggregation¹³⁴. These results are also consistent with a role for fibronectin in cell adhesion.

Cellular fibronectin does not appear to directly control cell growth rates, nutrient transport, or cyclic AMP levels. For example, these changes could not be reverted to normal after fibronectin treatment of transformed cells^{44,56,103,135}.

Protease experiments also provide additional evidence against a direct role for fibronectin in growth regulation. For example, treatment with papain or thermolysin removes all detectable fibronectin from the cell surface, but does not activate growth of chick fibroblasts¹³⁴. Conversely, thrombin activates cell division without removing cellular fibronectin^{136,137}. Insulin treatment can also stimulate mitosis without decreasing fibronectin⁷⁸.

Structure and composition

A current model for the structure of the fibronectins is shown in Fig. 2. Both plasma and cell surface fibronectins are probably elongated rather than globular proteins^{24,26,138} (contrast ref. 6). Plasma fibronectin is a dimer of two polypeptides of 220,000 each^{24,26}. Its subunits may not be identical, since analysis of plasma fibronectin after reducing disulphide bonds reveals a closely spaced doublet band^{24,26}. Cell surface fibronectin exists both as disulphide-bonded dimers and multimers^{31,139,140}. The interchain disulphide bridge(s) of both forms of fibronectin are confined to one end of the molecule, probably the carboxyl

terminus^{26,102,107,141,142}. This asymmetric location may serve to increase the asymmetry of the molecule. Reduction of disulphide bonds inhibits the effects of cellular fibronectin on cell–substratum adhesion¹⁴³. The amino termini of both forms are blocked^{24,26,51}, and their amino acid and carbohydrate compositions are very similar^{24,51,144,145}.

Information about the secondary and tertiary structures of these proteins are provided by circular dichroism and fluorescence measurements, respectively. Circular dichroism reveals little evidence for regular secondary structure in both molecules, since the optical activity is unusually low^{72,138}. Nevertheless, some folded regions appear to be present, since the tryptophan fluorescence spectrum suggests that at least some of the tryptophan residues are buried in hydrophobic regions of structure¹³⁸. Heating exposes the tryptophan sidechains, and destroys fibronectin's agglutinating activity^{50,138}. The fibronectins therefore appear to be floppy, asymmetric molecules, with localised regions of folding that may be important for adhesive activity.

Direct comparisons of the structures of fibronectins isolated from plasma and culture medium (which contains cell surface fibronectin secreted by cells) reveal very similar isoelectric points, migration in SDS–polyacrylamide gels, and cyanogen bromide cleavage products for proteins from these sources¹⁴⁵. However, there are several reports of slight differences in electrophoretic mobility between cellular and plasma fibronectins^{37,67,139}, and in some gel systems, the plasma form can be resolved as a doublet, whereas the cellular form is a single broad band^{20,24,26,37,172}.

The solubilities of the two proteins also differ. The plasma form is soluble at neutral pH²⁴, whereas the cellular form is insoluble unless the pH is elevated to pH 11 or it is treated with strong denaturing agents^{13,51,146,147}. The insolubility of cellular fibronectin may account for its aggregated distribution on the cell surface.

What accounts for these differences in solubility and electrophoretic mobility? Differences may exist in the amino termini of these proteins. For example, the differences in electrophoretic mobilities between these proteins are preserved even after the putative carboxyl terminal disulphide bonds are cleaved from the molecule by limited proteolysis with trypsin¹⁷². Human and bovine plasma fibronectins have amino terminal pyroglutamate residues^{24,26}, whereas chick cellular fibronectin does not⁵¹. One current speculation is that the two forms of fibronectin may be the same gene product, but the surface form is proteolytically processed to the slightly smaller plasma form. Alternatively, they may be produced by separate genes arising from gene duplication. Several laboratories are actively investigating these possibilities.

Carbohydrates of the fibronectins

The carbohydrates on cell surface fibronectin consist primarily of the 'complex' type of oligosaccharide linked by *N*-glycosidic bonds to asparagine. There are probably an average of 4–6 such oligosaccharide groups per molecule, containing terminal galactose, sialic acid, and fucose residues^{51,148,149}. The structure of the carbohydrate moieties of the plasma form of fibronectin are not known, although the compositions of the two forms are similar^{24,51,145,149}.

Treatment of cells with the antibiotic tunicamycin specifically blocks the formation of this class of oligosaccharide. Chick fibroblasts treated with tunicamycin produce unglycosylated fibronectin, and total amounts of this protein are substantially decreased^{148,150}. The decrease is not due to altered synthesis or secretion, but instead to increased proteolytic degradation¹⁴⁸. These results suggest that for cellular fibronectin, carbohydrates are not necessary for synthesis, processing, or secretion, but instead may function to protect the protein from proteolytic attack by cellular proteases.

Regulation of fibronectin

Quantities of cell surface fibronectin vary as cells traverse the cell cycle. Fibronectin levels are lowest on cells in mitosis by both radioactive surface labelling and immunofluorescence criteria, even though intracellular levels of fibronectin do not appear to vary significantly^{19,43,86,93}. This finding is of interest, since cells in mitosis also resemble transformed cells with respect to morphology, agglutinability by lectins, glycopeptide size, and loss of contact inhibition of movement¹⁵¹.

Even though fibronectin is decreased on cells during mitosis, the turnover rate of cell surface fibronectin is substantially longer than the cell cycle in chick cells (half remains after 36 h with an 18 h generation time; refs 55, 152; see also refs 21, 77, 86, 153). This apparent paradox could be explained if cells temporarily release themselves from the matrix of cell surface fibronectin during mitosis, and spread back into and rebind the same matrix as they re-flatten following cell division.

Growth conditions also influence quantities of cell surface fibronectin. For example, nonproliferating cells in dense cultures in the G1 phase of the cell cycle generally have larger amounts of fibronectin than rapidly growing cells^{15,19,47,83,85,86,93,98}. Cells prevented from dividing by serum deprivation can have either elevated¹⁹ or substantially reduced amounts of cell surface fibronectin¹⁵⁴. Mouse 3T3 cells cultured in media containing lowered concentrations of serum have little fibronectin; cell surface fibronectin levels are restored after treatment with epidermal growth factor, but not by other hormones¹⁵⁴. Fibronectin production by human fibroblasts is also reportedly stimulated by thrombin¹⁵⁵.

How fibronectin becomes depleted on the cell surface after malignant transformation has been studied in detail. Increased cell proteases after transformation cannot alone account for the loss of fibronectin^{84,87,156}. In chick fibroblasts transformed by several strains of tumour virus, the major factor in the decrease was found to be decreased biosynthesis⁵⁵, apparently due to decreased amounts of translatable messenger RNA¹⁵⁷. However, other factors also contribute to the decreases in fibronectin, including an increased rate of proteolytic degradation^{21,55,77} and a decreased capacity to bind the protein to the cell surface⁵⁵. In hamster cells, major factors in the loss of fibronectin after transformation also appear to be reduced biosynthesis and increased degradation^{107,158}. However, in human transformants, decreased capacity to retain the protein on the cell surface may be more important than its decreased synthesis^{30,52}.

Amounts of fibronectin on the cell surface are also regulated during embryonic differentiation. As *in vivo*⁵⁹, differentiation of muscle or cartilage cells *in vitro* is accompanied by a decrease in fibronectin on the cell surface^{47,159,160} (contrast ref. 98). Dedifferentiation of chondrocytes results in increased amounts of fibronectin^{160,174}. Experimental addition of cellular fibronectin to chondrocytes results in cells morphologically similar to undifferentiated mesenchymal cells that no longer synthesise the large amounts of sulfated proteoglycans characteristic of differentiated chondrocytes¹⁷⁵. Programmed losses of cellular fibronectin may, therefore, be a prerequisite for differentiation of certain cells.

These studies on the regulation of fibronectin levels on the cell surface indicate that control can be exerted by a variety of events including altered growth conditions, transformation, hormonal stimulation, and embryonic differentiation. This regulation may occur through altered synthesis, turnover, or binding to the cell surface.

Relationship of fibronectin to cytoskeletal and membrane components

The overall organisation of cell surface fibronectin into fibrillar patterns parallel to the long axis of cells is roughly similar to that of intracellular microfilament bundles⁴⁰. However, immunofluorescence studies comparing fibronectin and actin localisation patterns have shown that the two patterns

need not coincide (ref 32 and our unpublished results). These findings suggest that there may not be direct transmembrane connections between microfilament bundles and all of the surface fibronectin.

However, indirect associations or discrete attachment points may occur. For example, cell surface fibronectin is concentrated on the lower surface of cells¹⁶¹, and particularly in the adhesive attachment sites of cells to substrata¹⁶². Treatment of cells with low concentrations of proteases or anti-fibronectin can result in cell rounding and in a loss of microfilament bundle organisation^{34,163}. Treatment of transformed cells missing microfilament bundles with fibronectin permits reorganisation of intracellular microfilament bundles^{56,104}, perhaps due to increased cell-substratum adhesion that permits anchoring of these bundles (Fig. 3).

Conversely, cytoskeletal elements may also affect the organisation of cellular fibronectin. Treatment of cultured cells with cytochalasin results in a release of fibronectin from the cells, suggesting a possible requirement for microfilament integrity in maintaining fibronectin organisation^{164,165}. Treatment of cells with anti-fibronectin can result in antibody-induced redistribution of fibronectin¹⁶⁶ to 'caps' of antigen on the upper surfaces of cells³⁴. This process requires metabolic energy, and is inhibited by a combination of colchicine and cytochalasin³⁴; cytoskeletal elements may also be involved in this redistribution. More detailed analyses of the ultrastructural and biochemical relationships of these proteins should provide further insight into fibronectin-cytoskeletal interactions.

Fibrillar networks of cell surface fibronectin are relatively immobile by comparison with mobility of other cell surface components. For example, receptors for concanavalin A move with a diffusion constant of $4 \times 10^{-11} \text{ cm}^2 \text{ s}^{-1}$, while fibronectin's is $< 5 \times 10^{-12}$ (ref. 42). As cellular fibronectin is relatively immobile, it might inhibit the mobility of other components of the cell surface. The movement of gold particles on the upper surfaces of 3T3 cells is inhibited by fibrils of cellular fibronectin¹⁶⁷. In contrast, the mobilities of a ganglioside analog, a lipid probe, and a mixture of surface antigens are not affected by the presence of fibronectin fibrils⁴². It is therefore possible that fibrillar networks of fibronectin affect interactions of cells with large objects such as particles, cell processes, or substrata, whereas smaller membrane components remain unaffected. These results are consistent with the location of fibronectin fibrils close to, but not necessarily tightly apposed to, the plasma membrane.

Future prospects

Although we know the overall structure, location, and probable general functions of the fibronectins, many important questions remain. For example, although the fibronectins are adhesive proteins, it is not clear how they function *in vivo*—for example in organising the extracellular matrix, cell migration, wound healing, macrophage ingestion of colloids, hemostasis, and embryogenesis. Is this protein directly involved in inhibiting tumorigenicity or metastasis *in vivo*? Is its role in the reticulo-endothelial system confined to the removal of collagenous debris, or does it play a wider role in host defense^{168,169}? Other interesting problems concern the precise differences in structure and regulation of the plasma and cell surface forms of fibronectin, their possible relationships to other more specific adhesive molecules that appear at precise times in vertebrate embryonic development¹⁷⁰, and the biophysical mechanisms by which these proteins can bind to cells and to substrata.

and

Dept of Plasma Physics, Royal Institute of Technology, 100 44 Stockholm, Sweden

Recent in situ measurements have led to a substantial revision of our picture of the magnetosphere and parts of the heliosphere. This concerns the character and distribution of electric fields and currents, the ways in which charged particles are energised, and the chemical composition of the magnetospheric plasma. This revision reflects the fact that real cosmic plasmas behave in fundamentally different ways than predicted by the traditional, idealised models used in magnetospheric physics and in astrophysics. The new understanding of the general properties of cosmic plasma gives us an improved basis on which to interpret astrophysical observations.

ASTRONOMY, and especially astrophysics, is in an interesting phase, where remarkable observational discoveries are being made. However, since astrophysical phenomena occur in remote regions, where *in situ* observations are not possible, and involve matter in various extreme states, it can be difficult to understand the physical phenomena behind them. Usually the states involved are magnetised plasmas at extremes of temperatures and/or density. The interpretation of the observations then depends on whatever knowledge of plasma processes is available.

The difficulties involved can be understood by recalling those faced by thermonuclear fusion research 20 years ago. The task was to predict the behaviour of a very hot, magnetically confined, plasma. A well developed theoretical formalism existed. It was the classical theory of gases, generalised to include charged particles, but it had not been subjected to a thorough experimental verification. It was found that the hot plasmas in thermonuclear machines often behaved quite differently from what had been predicted from existing plasma theories. This necessitated a fresh start, with experiments as the backbone of the theoretical structures. However, even now the complicated behaviour of hot, magnetically confined plasma is far from being completely understood.

In astrophysics the situation is more difficult because, in contrast to the plasmas in thermonuclear machines, *in situ* 'diagnosis' of the astrophysical objects is not possible. The coming of the space age means that cosmic plasma can now be studied *in situ*, but only in our near-space environment.

To understand the significance of this, it is important to realise that our immediate environment in space, the magnetosphere (including the ionosphere) of the Earth and the adjacent interplanetary space, offer a rich sample of plasma

states in natural conditions. They include cool, weakly ionised, collision-dominated, gravity confined plasmas as well as hot, essentially fully-ionised and virtually collisionless magnetically confined plasmas. While the parameters may still be many magnitudes less than the extreme values attained in some remote astrophysical plasmas, the plasmas in the magnetosphere are a large step from the parameter range available in Earth-based laboratories. Study of the magnetospheric plasmas can, therefore, greatly widen the empirical basis of cosmic physics.

Spacecraft observations in the magnetosphere have already identified various plasma processes which were not predicted from classical kinetic theory, the MHD formalism or even modern plasma theories. In particular, as we point out below, limitations have been found to the validity of the classical concept of the frozen-in-magnetic field, which used to be a 'golden rule' in cosmic electrodynamics.

The need for an improved empirical basis in cosmic physics is dramatically illustrated by the history of magnetospheric research itself. Before *in situ* measurements were possible, and even for many years after satellite measurements had begun, the magnetosphere was described in terms of highly idealised models that were a heritage from classical plasma physics. They involved infinite conductivity along magnetic field lines, frozen-in-magnetic fields and simple magneto-hydrodynamic convection. It was tacitly assumed that the matter in the outer magnetosphere was (mainly) hydrogen ions from the solar wind, and that electric fields—if they were considered at all—were everywhere transverse to the magnetic field.

For a long time even spacecraft observations failed to reveal the fallacy of such assumptions, this was probably because their indiscriminant use guided the planning and design of the observations. Thus, for example, particle detectors in low Earth orbit always looked upwards because accelerated particles coming from below—as have been recently observed—were inconceivable in the prevailing theories.

Only during the past few years, has the magnetospheric physicist found that the classical concepts break down in certain interesting regions of the magnetosphere. Also, only during the past few years, have the significance of Birkeland currents (magnetic-field-aligned electric currents in the magnetosphere) and magnetic-field-aligned electric fields been realised. This has far-reaching consequences in understanding the aurora and other phenomena in the magnetosphere.

Although the understanding of the magnetosphere has increased gradually a veritable breakthrough has resulted from a few particle and field measurements on one single satellite,

S3-3. We now know that: (1) the frozen-field condition is not reliable, and different levels of the magnetosphere can be electrically decoupled—at least partially; (2) magnetic-field-aligned electric fields with potentials of several kV exist not only in narrow regions but over hundreds of km in latitude; (3) ionospheric ions are accelerated along the geomagnetic field into the magnetosphere; and (4) large, sometimes dominant part of the storm time ring current consists of oxygen from the ionosphere rather than hydrogen from the solar wind.

Such discoveries in magnetospheric physics indicate that the really important phase of magnetospheric research, in terms of fundamental physical understanding of plasma behaviour in natural conditions, has only just begun.

This will also have far-reaching consequences for the foundations of cosmic plasma physics and hence for astrophysics. If a cosmic plasma system which is so close to us could, for such a long time, be misinterpreted in terms of the physical processes going on, how confident can we be of the interpretations of the astrophysical phenomena known only by remote observations? Kelvin estimated the age of the Earth, on the basis of its cooling rate, to be 50 Myr because radioactivity was not known during his generation. Inadequate plasma physical models could lead to—and have already led to—similarly misleading conclusions in astrophysics.

It is worth emphasising the importance of laboratory experiments in cosmic plasma physics. In thermonuclear research a great deal of progress has been possible, after the initial setback, because a large experimental effort has guided the theoretical development. Similarly, in cosmic plasma physics, laboratory experiments, as well as magnetospheric research, are needed to guide the theoretical interpretation of remote observations. One example is the electric double layer phenomenon, which according to recent observations is likely to occur in the magnetosphere and may have profound consequences in cosmic plasmas. Although its existence has long been known in unmagnetised plasma, and recently proved in magnetised plasma, an adequate theory—especially of its dynamics—does not yet exist, and in all applications one must rely on results of laboratory experiments.

The role of magnetisation

Virtually any known astrophysical plasma is magnetised. To be precise, a magnetised plasma is defined as a plasma that contains a magnetic field which is strong enough to make the gyroradii of all its charged particles much smaller than the linear dimensions of interest. As the latter are usually large in cosmic plasmas, even a small magnetic field is sufficient to make the plasma magnetised.

For example, for stellar dimensions and temperatures of the order of 10^6 K, as in the corona, magnetic fields above 10^{-12} T are sufficient. For galactic dimensions, and even if we consider the highest observed energies, the corresponding number is 10^{-17} T. The smallest cosmic magnetic fields which can be measured or inferred are of the order of 10^{-9} T.

For magnetised plasmas it is often useful to distinguish between three classes: high, medium and low density plasmas¹. They are defined in terms of the relative magnitudes of the gyroradius, ρ , the mean free path, λ , and the characteristic linear scale, l_0 , as follows:

High density, $\lambda \ll \rho$; medium density, $\rho \ll \lambda \ll l_0$; low density, $l_0 \ll \lambda$.

High density plasmas occur in stellar bodies, lower stellar atmospheres and lower planetary ionospheres. Except for wave propagation they have a high degree of isotropy. Current densities and electric fields obey a simple local relationship—Ohm's law.

Medium density plasmas prevail in fairly thin transition regions above the lower stellar atmospheres and planetary ionospheres, but can also occur in regions such as the Earth's plasmasphere. These plasmas are anisotropic in terms of

diffusion and electric current conduction. The electric field-current density relation is still local and can be expressed as a generalised Ohm's law.

Low density plasmas prevail throughout most of the Earth's (and other) magnetosphere(s), the solar corona, interplanetary, interstellar and intergalactic space. They are the most complicated plasmas, because collective interactions tend to be important instead of the relatively simple binary collisions that prevail in low and medium density plasmas. Numerous kinds of plasma instabilities and wave-particle interactions are possible. In terms of electric properties, a major complication is that there need no longer exist any local relationship between electric field and current density. The reason is that charge carriers may gain momentum from the electric field in one region and lose it, for example, by magnetic mirroring, in a different region. Low density plasmas in this sense are a major preoccupation of modern plasma physics, especially in thermonuclear research where $\lambda \gg l_0$ is one of the requirements for magnetic confinement.

In the magnetosphere, the most exciting discoveries in recent years are related to the properties of low density plasmas. The consequences for the understanding of cosmic physics in general can be expected to be far reaching.

Electric currents and fields in cosmic plasmas

The magnetisation of all cosmic plasmas is connected with electric currents through Maxwell's first equation $\text{curl } \mathbf{B} = \mu_0 \mathbf{j}$ and as cosmic magnetic fields are not generally curl-free, a fundamental problem is how electric currents are carried by cosmic plasmas².

For high and medium density plasmas this is a simple problem, because the current is determined essentially by a local balance between electric, magnetic and frictional forces. The current-carrying ability of the medium at each point is characterised by a conductivity which in high density plasmas is a scalar, in medium density plasmas a tensor.

In low density plasmas the conduction of current is complicated. This fact is often overlooked, and classical conductivity formulas are erroneously applied to low density cosmic plasmas. One illusion is that, as collisions become rare and vanish, the conductivity along magnetic field lines increases and becomes essentially infinite. In reality, the concept of conductivity will lose its meaning¹. There need not be any local relation such as Ohm's law.

Magnetospheric spacecraft observations in the past few years have shown that the conductivity concept is obviously misleading. This has great consequences in many astrophysical applications, too. In particular, the ability of a low density plasma to carry electric current is far from being 'infinite', and substantial electric fields can be required to drive the Birkeland currents (magnetic-field-aligned currents) of the magnitude (of the order of 10^{-6} A m⁻²) observed in the magnetosphere. This greatly affects astrophysics, because first it changes the whole electrodynamic of cosmic plasma; second, the finite electric field along magnetic field lines violates the concept of frozen-in magnetic field lines, and finally it provides an efficient means of particle acceleration.

A few typical phenomena will now be briefly described that involve substantial magnetic-field-aligned electric fields.

Anomalous resistivity has been recognised for over a decade as a possible means of supporting magnetic-field-aligned electric fields in space plasma (for a review see ref. 3). Anomalous resistivity is characterised by wave-turbulence sufficiently strong to impede the current-carrying electrons so that a local Ohm's law is reestablished. The wave turbulence is usually considered to be driven by the current itself, but may also be maintained by a separate agent such as a high-energy electron beam that is unstable in the local plasma environment^{4,5}. Whatever the cause may be, the d.c. electric field strength, E , that can be supported is limited by the condition $E \ll E_{\text{max}}$,

where E_{rms} is the r.m.s. value of the electric field of the wave turbulence⁷. This has been confirmed by direct measurements in the magnetosphere⁸.

The wave turbulence will act differently on particles in different parts of velocity space. Particles of sufficient initial velocity (in the direction of the electric force) will become runaways, that is, decoupled from the main population of charge carriers, and the current they carry will not be determined by local conditions but depend on the whole electric circuit involved. Therefore, if the runaway current becomes substantial compared to the total electric current, the local relationship between electric field and current is lost. Thus the current is not determined by local 'resistivity', and the whole circuit must be taken into account. Then the term 'resistivity' loses its meaning.

The anomalous resistivity phenomenon has been established by laboratory experiments (for a review, see ref. 9) and wave fields measured in the magnetosphere (for a review, see refs 10, 11) are large enough to support magnetic-field-aligned electric fields of the order of mV m^{-1} , which may integrate to voltage drops of the order of several keV, a field large enough to be of significance to magnetospheric plasma dynamics. On the other hand, in the magnetosphere, anomalous resistivity may not be the only, or even the most important, mechanism for supporting magnetic-field-aligned electric fields. Alternative mechanisms are the double layer and the magnetic mirror effect.

The electric double layer was discovered by Langmuir in 1929 but wide interest in the phenomenon has been revived recently by experiment studies¹²⁻¹⁴. For cosmical applications it is essential that its existence in magnetised plasma has now been proved^{15,16}. (For a review with special reference to possible space applications, see refs 17, 18.)

Like anomalous resistivity, a double layer is typically established as a consequence of current-driven plasma instabilities. To predict whether the end result of a given instability will be anomalous resistivity or a double layer is difficult. Theoretical studies have therefore often started with the assumption that the end state is one of anomalous resistivity.

The laboratory experiments which show that the result of the instability may well be a double layer instead of anomalous resistivity, illustrate the danger of a purely theoretical approach and the need for empirical experiments on the behaviour of the real plasma.

The electric potential drop across a double layer depends on factors such as density and temperature of the adjoining plasmas and on the electric properties of the circuit in which the current is closed. Thus, unlike anomalous resistivity, the electric double layer does not imply a local relationship between electric field and current density.

Double layers and anomalous resistivity differ in the way that the dissipated energy is deposited. In the case of anomalous resistivity, it is deposited in the ambient plasma at the location of the voltage drop, leading to intense local heating there. In the case of a double layer, all particles passing through the layer are 'runaways', and form beams that carry away the dissipated energy to be deposited in some other region where the beam is finally stopped. In the magnetosphere, this may account for the energy deposition in the polar ionosphere by auroral primaries without excessive heating in the acceleration region. In many astrophysical applications such remote deposition of energy may be very important.

Direct observations of double layers are difficult because they are relatively thin, 10–100 Debyelengths. The probability of encountering a double layer is one in several hundred satellite passes. In the recent electric field data of the S3-3 satellite⁸ there is one case (from about 200) where the magnetic-field-aligned electric field was reported to be several hundred mV m^{-1} . This is compatible with an electric double layer¹⁹.

In a low density plasma situated in a magnetic mirror field slight differential anisotropies between positive and negative

particles can lead to large magnetic-field-aligned electric fields even without a net current¹. In the magnetosphere where large field-aligned currents (Birkeland currents) flow to and from the auroral oval, and in many astrophysical situations, the magnetic mirror effect puts an upper limit to the conductance per unit area—a conductivity need still not exist—which above the auroral region of the Earth is at most of the order of a few $\text{A m}^{-2} \text{keV}^{-1}$ (refs 7, 20). This requires that the loss cone of the source plasma is continually replenished. If it is not, the current will be choked and the conductance reduced to still smaller values and can in principle approach zero.

The frozen field condition

If the classical conductivity formula were applicable to cosmic plasmas, the condition for 'frozen-in magnetic fields' would almost always be fulfilled. But the plasma properties described above may well decouple the electric fields in different portions of a magnetic flux tube (magnetic field unfreezing). This occurs at least in a limited region of the magnetosphere above the auroral ovals. Recent observations of comet tails²¹ are apparently the first proof of magnetic-field unfreezing in plasmas outside the Earth's magnetosphere.

Magnetic field unfreezing may also invalidate the law of isorotation, and in the context of planet and satellite formation allow an important phenomenon called partial corotation²².

Particle acceleration

Cosmic plasmas can generate suprathermal and high energy particles. In ordinary particle accelerators, insulators and sometimes also tuned harmonic signals are requisites for accelerating charged particles to high energy. None of these requisites are available in cosmic plasmas. Yet we observe cosmic ray particles with energies of 10^{10} eV or more, solar protons of 10^{10} eV and magnetospheric protons of $1\text{--}10^6$ eV. It would be difficult to generate such high-energy particles if the plasma had the simple magnetohydrodynamic properties usually ascribed to it.

Some particle energisation processes in cosmic plasma can be studied in the magnetosphere. Their products range from slightly suprathermal electron fluxes in the ionosphere to ions of several MeV in the radiation belts and in the tail region of the magnetosphere. Some of these acceleration processes involve wave fields due to various instabilities. Others depend on slowly fluctuating transverse electric fields to cause drift-resonant adiabatic acceleration, which can be compounded with non-adiabatic effects. An interesting process is the direct acceleration of charged particles in the magnetic-field-aligned electric fields that regularly occur in low density plasmas. This possibility was previously excluded by the assumption that magnetic-field-aligned electric fields cannot exist and that the frozen-field condition is always valid. In the magnetosphere, such a direct acceleration process seems to play an important part in auroral phenomena^{7,17,18,23,24}. In the solar atmosphere the field-aligned acceleration may also play an important part in flare phenomena²⁵, which is widely recognised to have many similarities with magnetospheric substorms²⁶. Field-aligned acceleration may also be important in many other cosmic plasmas. One example on a large linear scale is double radio sources²⁷. The energy, originating in the unipolar dynamo of the central galaxy, is carried by electric current to the two opposite remote regions where the current becomes unstable and a parallel electric field is established (presumably in a double layer).

The structure of matter in space

One of the most important results of space exploration is the discovery of a number of boundary surfaces. Some of these layers are due to electric sheet currents which may reverse the magnetic field. This often occurs in the magnetopause, in the neutral sheets of the magnetotail, in the solar equatorial plane² (previously interpreted as 'the sector structure'), and in

cometary tails²¹. Such boundary sheets may be very thin, sometimes only a few Larmour radii. Their persistence demonstrates that they have a high degree of stability and that cosmic plasmas have a general tendency to divide themselves into compartments by setting up such layers.

The discovery of the many boundaries separating different plasmas is remarkable in that neither theoretical considerations nor laboratory experience had led us to expect layers with the observed properties (although other types of layers were predicted). This is very important for our picture of the structure of space. We find that space occupied by plasmas tends to be divided in 'compartments', often separated by thin current sheets. On the interstellar and intergalactic scale, space may have a cellular structure consisting of many separate regions, containing plasmas of different magnetisation, density, temperature, and perhaps also different kinds of matter (koino- and antimatter).

Conclusions

For a proper understanding of astrophysical phenomena, the theoretical work must be guided by empirical knowledge of how plasmas behave in nature. Laboratory experiments have an essential role in this context but *in situ* observations of the magnetospheric plasma can, in some respects, provide us with an even better knowledge of plasma behaviour in natural conditions. The plasma in the magnetosphere (including the ionosphere) and the solar wind are the only cosmic plasmas accessible to extensive *in situ* observations and experiments.

Observations of magnetospheric plasmas extend our empirical knowledge to a new range of plasma parameters by many powers of 10. It is also fortunate that the Earth's magnetosphere contains such a rich variety of plasmas, from the relatively dense and cool ionospheric plasma to the extremely thin and hot plasmas at larger distances.

The truly fundamental progress in the understanding of the

magnetosphere has only just begun. It has begun because of the recent observational discoveries which mark a new phase of magnetospheric research. The knowledge already obtained, and the insights still to be gained, in this new phase of magnetospheric research should be of great value in understanding astrophysical plasmas and may lead to similar drastic revisions in astrophysics.

Young's double beam interference experiment with spinor and vector waves

J. Byrne

School of Mathematical and Physical Sciences, University of Sussex, Brighton, Sussex, UK

The fringe shift observed in Young's double beam interference experiment using unpolarised neutrons, when one beam traverses a magnetic field before recombination, has been interpreted as implying direct observation of the sign reversal of a spinor wave function subjected to a 2π rotation. This interpretation is unsatisfactory because for any fermion the relative rotation of the spins in the two beams and the interference pattern are mutually incompatible observables. This incompatibility does not arise in the case of bosons which possess a state of zero spin-component. Furthermore, equivalent 'sign-reversal' effects may be observed in interference phenomena associated with any two-state system and a realisable photon analogue is proposed.

RAUCH ET AL.¹ and Werner *et al.*² have independently described neutron analogues of Young's double slit optical interference experiment using unpolarised neutrons which have been interpreted as a direct observation of the sign rever-

sal of a fermion wave-function under a 2π rotation. In these experiments, amplitude division of a coherent neutron wave train is brought about by a symmetrical Laue reflection in a single crystal of silicon. One of the emergent beams traverses a uniform magnetic field while the other propagates in a field-free region. The crucial result is the observation that the interference pattern formed where the two beams recombine, shifts through half a fringe when the magnetic field is varied from zero to a value such that the spins of those neutrons moving through the magnetic field precess through an angle of 2π relative to the spins of those neutrons which move in the field free region^{3,4}.

Interference pattern

This extremely elegant technique provides an interferometric method of distinguishing fermion from boson⁵ because the equivalent boson interference pattern would shift through a full fringe. One must, nevertheless, be cautious about the claim² that "we have directly observed the sign reversal of the wave function of a fermion produced by its precession of 2π radians in a magnetic field using a neutron interferometer". The difficulty relates to the notion of 'relative rotation'³⁻⁷ as applied

to the fermion spins in the context of an interference experiment as, for fermions, simultaneous observations of the relative rotation of the spins in the two beams and of the phase shift are incompatible. We may, of course, measure the angle of rotation of those neutron spins constrained to move in the magnetic field relative to the spins of neutrons in the field-free region. An essential feature, however, of all interference phenomena is that, whereas the wave amplitudes propagate along distinguishable paths, all information concerning which path the neutron actually follows is lost⁶. In these circumstances the notion of relative rotation ceases to have a meaning as it corresponds to nothing which is measurable. The objection therefore is founded on the uncertainty relation and is not pedantry because, as we show below, no equivalent inconsistency arises in the case of bosons.

Let u_0 be the incident spinor, then the neutron wave train reaching the detector in the absence of the interferometer is represented by the spinor $u_0(x) = u_0 e^{i\phi_0 x/\hbar}$. When the interferometer is introduced $u_0(x)$ is transformed to

$$u(x) = \begin{bmatrix} A + B e^{-i\alpha/2} & 0 \\ 0 & A + B e^{i\alpha/2} \end{bmatrix} u_0(x) = M u_0(x) \quad (1)$$

where A and B are real parameters characterising the amplitudes of the interfering beams and $\beta = -geBx/2p_0$ (ref. 3). The action of the interferometer is described by the transfer matrix

$$M = \begin{bmatrix} T^{1/2} e^{-i\alpha/2} & 0 \\ 0 & T^{1/2} e^{i\alpha/2} \end{bmatrix} \quad (2)$$

where T , the matrix determinant, is given by

$$T = A^2 + B^2 + 2AB \cos(\beta/2) \quad (3)$$

and

$$\tan\left(\frac{\alpha}{2}\right) = \frac{B \tan(\beta/2)}{B + A \sec(\beta/2)} \quad (4)$$

As M describes a transformation to a state whose normalisation has been multiplied by $T^{1/2}$, we may interpret T as the transmission coefficient for the interferometer. It follows from equation (3) that the interference pattern has a minimum at $\beta = 2\pi$ and the fringe visibility V is therefore

$$V = 2AB/(A^2 + B^2) \quad (5)$$

The observation of the interference pattern exhausts the experimental possibilities for unpolarised neutrons.

Because there is no uncertainty relationship between spin and position it is possible, using polarised neutrons, to make simultaneous measurements of the interference pattern and of the neutron spin polarisation at each point along it. The additional information may be derived from the density operator ρ which according to equation (2) is transformed to

$$\rho_i(x) = M \rho_0(x) M^{-1} = \begin{bmatrix} \rho_{11}^0 & \rho_{12}^0 e^{-i\alpha} \\ \rho_{21}^0 e^{+i\alpha} & \rho_{22}^0 \end{bmatrix} \quad (6)$$

The polarisation P_i of the transmitted beam is defined by

$$P_i = \langle \sigma_i \rangle = \text{Tr}(\rho_i(x) \sigma_i) / \text{Tr}(\rho_i(x)) \quad (7)$$

and in particular

$$P_x = P_{x0} \quad (8a); \quad (P_x + iP_y)_i = (P_x + iP_y)_0 e^{i\alpha} \quad (8b)$$

The essential results are contained in equations (8) showing that although the component of the neutron polarisation in the recombined beam parallel to the magnetic field is unchanged from what it was before the division of amplitude, the polarisation vector in the plane transverse to the magnetic field is rotated through an angle α . Thus, although the density matrix contains sufficient information to allow us to make predictions about the absolute rotation of the neutron spins in the recombined beam it contains no information about the relative rotation of the spins in the constituent beams. The essential point is, of course, that whereas the phase difference β between the

spatially separated wave trains is determined by the mag. field and the passage time alone, the absolute angle of rotation α of the polarisation vector in the reconstituted beam also requires for its specification the mixing ratio B/A of the component wave trains as expressed through equation (4).

To emphasise the significance of these results from an experimental viewpoint we might envisage carrying out two limiting types of measurement. In the first case we set $A < B$ and determine the spin rotation of the transmitted neutrons which reaches the value π at $\cos \beta/2 = -A/B$, making the transition to 2π at $\beta = 2\pi$. Alternatively we can set $A > B$ in which case α achieves a maximum deviation of $2 \tan^{-1}[(B/A)/(1 - (B/A)^2)^{1/2}]$ at $\cos \beta/2 = -B/A$ and then drops rapidly back to zero at $\beta = 2\pi$. Thus the polarisation in the recombined beam carries out a rotation for $A < B$ and a nutation for $A > B$. There is no 'relative rotation'. When either A or B tends to zero the polarisation approximates to that of neutrons whose paths are constrained but the fringe visibility reduces in proportion.

At the other limit we set $A = B$ with unit fringe visibility and, as $\beta \rightarrow 2\pi$, we find that $\alpha \rightarrow \pi$ and the polarisation in the transmitted beam is reversed. Evidently there is a discontinuity in α at $\beta = 2\pi$ in the transition from $A < B$ to $A > B$ which means that at maximum fringe visibility the spin rotation becomes indeterminate at the interference minimum.

Apparently we must omit the case $A = B$, representing a fringe visibility of unity and total polarisation reversal, because in this situation the transfer matrix is null at the interference minimum and no neutrons are transmitted. However, this results from a defect in the formalism which uses plane wave states; in the more realistic wave packet description the factor $\cos \beta$ in equation (3) is replaced by the real part of, and the visibility $V < 1$ by the modulus of, the complex degree of coherence in the interfering wave trains, thus the reduction of the transfer matrix to singular form is avoided.

Bosons

The equivalent situation for bosons may be explored by treating the case of a spin 1 particle whose spin wave-function is characterised by three independent amplitudes a_+ , a_0 , a_- , corresponding to states with spin component $M = 1, 0$ or -1 along the magnetic field. The density matrix now has 9 elements which may be organised into subsets of 1, 3 and 5 elements which are the expectation values of spherical tensors of rank 0, 1 and 2 respectively^{9,10}. The first rank tensor moments are just the components of the spin polarisation.

$$P_x = (|a_+|^2 - |a_-|^2)/I \quad (9a)$$

$$P_x \pm iP_y = \langle a_+^* a_0 + a_-^* a_0^* \rangle / \sqrt{2} I \quad (9b)$$

where $I = |a_+|^2 + |a_0|^2 + |a_-|^2$ is the total intensity.

In the presence of a magnetic field the amplitudes $a_{\pm}$ are shifted in phase to $a_{\pm} e^{i\alpha/2}$ and it should be noted from equation (9) that the transverse polarisation is linear in these amplitudes and their complex conjugates. The amplitude a_0 is unaffected by the magnetic field and this is crucial to the analysis since it follows that the transverse polarisation in the recombined beam does not contain any interference terms derived from products of field-dependent amplitudes. For spin 1 particles, equations (8) therefore become

$$P_x = P_{x0} \cdot (A^2 + B^2 + 2AB \cos \beta) / T \quad (10a)$$

$$(P_x \pm iP_y)_i = (P_x \pm iP_y)_0 ((A+B) \cdot (A+B e^{i\alpha})) / T \quad (10b)$$

where in this case the transmission

$$T = A^2 + B^2 + 2AB \cos \beta + 2AB(1 - \cos \beta)(|a_0|^2/I)_0 \quad (11)$$

is sensitive to the degree of alignment $|a_0|^2/I$ in the beam incident on the interferometer.

Equation (10b) exhibits the fundamental feature that the term $(A+B) \cdot (A+B e^{i\alpha})$ may be represented as the incoherent sum of a fixed polarisation $(A+B)A$ and a rotating

196 $\sin(A+B)B e^{\pm i\theta}$ whereas for spin $\frac{1}{2}$ fermions there is (rotating) term derived from the coherent superposition of field dependent amplitudes. The weights $(A+B)A$ and $(A+B)B$ are identical with the weights A^2 and B^2 obtained by incoherently superimposing the constituent beams, for the case of maximum fringe visibility but this is an important point as the presence of the two terms allows us to give an operational meaning to the concept of relative rotation in the recombined beam whatever their relative magnitude.

To show that the concept of 'relative spin rotation' retains a meaning for bosons in the setting of an interference experiment we only have to examine the corresponding predictions for the two limiting experiments discussed above in the case of fermions. When $A \rightarrow 0$ and the fringe visibility becomes vanishingly small we find from equation (10) that the transmitted polarisation vector rotates through the angle β as expected. When $B \rightarrow 0$ there is no rotation and the angle β between the two orientations of the analysing axis of a filter giving maximum transmission for these two cases defines the relative rotation in the absence of interference. At the opposite extreme, where $A \approx B$ and the fringe visibility is maximum, there are two groups of neutrons, with relative intensities $(A+B)A$ and $(A+B)B$ respectively, that is those whose spins have suffered no deviation and those whose spins have rotated through the same angle β . We can again measure the relative rotation, the same relative rotation β as for the case of zero interference, by observing the two directions of the analysing axis of the filter which permits free passage to neutrons. This is quite different to the fermion case where there is transmission at a single angle $\alpha \neq \beta$ only and no method of measuring a relative rotation.

Not surprisingly we find from equation (11) that the intensity in the interference pattern for bosons reaches a maximum when $\beta = 2\pi$. The minima in the interference pattern occur at $\beta = \pm\pi$ and it is interesting that the transverse polarisation vanishes at the minima, when conditions are such as to maximise the fringe visibility.

To examine the behaviour of the vector polarisation does not exhaust the possibilities where spin 1 particles are concerned because the second rank tensor moments are also experimentally accessible quantities. Denoting these moments by $t_{1,M}$ (refs 9, 10) we find

$$\begin{aligned} (a) \quad t_{2,0} &= (1/\sqrt{2})(|a_+|^2 - 2|a_0|^2 + |a_-|^2) \\ (b) \quad t_{2,\pm 1} &= (\sqrt{3}/2)(a_+ a_0^* - a_-^* a_0) \\ (c) \quad t_{2,\pm 2} &= \sqrt{3} a_+^* a_- \end{aligned} \quad (12)$$

Clearly the magnetic field-dependence of the moments $t_{2,0\pm 1}$ is the same in essential respects as that of the moments $t_{1,0\pm 1}$ whose cartesian components are given in equation (9). The tensor moments $t_{2,\pm 2}$ behave quite differently in a magnetic field in that they are shifted in phase by $e^{\pm 2i\theta}$ when the amplitudes $a_{\pm}$ collect phase factors $e^{\pm i\theta}$. Therefore $t_{2,\pm 2}$ revert to their original values when $\beta = \pi$ and the amplitudes $a_{\pm}$ change sign. Thus $t_{2,\pm 2}$ are totally analogous to the components of the vector polarisation of a spinor field.

Sign reversal effects

Clearly then where 'sign reversal' effects are sought, the number of states available to the particles is not crucial, the important thing is that two of the participating states should be phase shifted in opposite directions by the application of a suitable perturbation. This has been demonstrated by Klemp¹¹ who observed sign reversal effects for transitions between the hyperfine levels of the diatomic molecule TIF. The experiments were carried out on a molecular beam resonance apparatus using the Ramsey separated oscillatory coil technique. Thus, although both sign reversal and interference effects were generated in spin space the underlying principle was the same as for neutron double beam interference.

The distinction between the results derived for spin $\frac{1}{2}$ and spin 1 particles in the case of the vector polarisation has been

traced to the existence in the latter case of a state, the $M=0$ state, whose amplitude is insensitive to the presence of the magnetic field. It follows, therefore, that the spin $\frac{1}{2}$ results are characteristic of all fermions, whereas the spin 1 results are characteristic of all bosons of non-vanishing spin for which an $M=0$ state exists. The single known boson excluded by this criterion is, of course, the photon for which the spin state can be defined only with respect to the momentum with the $M=0$ state disallowed because of the vanishing rest-mass.

In the neutron interferometer the magnetic field causes the neutron spins in one arm to alter their state from positive helicity to negative helicity and back again. A photon analogue would require the role of the magnetic field to be filled by an optical element which converts right circular polarisation to left circular polarisation and back again to right circular polarisation. Two half wave plates in series perform precisely these functions and a full wave plate introduces a phase difference of 2π between the polarisation states exactly as a magnetic field does for the neutron spin-states. Indeed Bernstein, who first thought of the neutron interference experiment³ specifically compares the action of the magnetic field to that of a birefringent medium.

The active element in the interference experiment proposed above is a uniaxial crystal with its optic axis normal to the direction of propagation of the beam. If a_x and a_y represent the components of the complex vector potential parallel and perpendicular respectively to the optic axis then the amplitudes $a_{\pm}$ for states with spin component $M = \pm 1$ along the momentum are

$$a_{\pm} = \mp(1/\sqrt{2})(a_x \mp ia_y) \quad (13)$$

Thus the circular polarisation P_c in the beam is given by

$$P_c = i(a_x a_y^* - a_x^* a_y)/I \quad (14)$$

where

$$I = \langle |a_x|^2 + |a_y|^2 \rangle \quad (15)$$

is the intensity.

The relationship between outgoing and incoming amplitudes in the light beam traversing the crystal may now be expressed as

$$\begin{pmatrix} a'_x \\ a'_y \end{pmatrix} = \begin{pmatrix} e^{i\delta_x} & 0 \\ 0 & e^{i\delta_y} \end{pmatrix} \begin{pmatrix} a_x \\ a_y \end{pmatrix} = e^{i\Delta/2} \begin{pmatrix} e^{i\delta/2} & 0 \\ 0 & e^{-i\delta/2} \end{pmatrix} \begin{pmatrix} a_x \\ a_y \end{pmatrix} \quad (16)$$

where

$$\begin{aligned} \delta_x &= \frac{2\pi}{\lambda} n_o z & \delta_y &= \frac{2\pi}{\lambda} n_E z \\ \Delta &= (\delta_x + \delta_y) & \delta &= (\delta_x - \delta_y) \end{aligned} \quad (17)$$

z is the path length in the crystal, and n_o and n_E are the ordinary and extraordinary indices of refraction.

It follows from equations (14) and (16) that, for a beam prepared in a state of pure circular polarisation P_c without ellipticity, the output circular polarisation P'_c is given by

$$P'_c = P_c \cos \delta \quad (18)$$

Thus, the circular polarisation is reversed when $\delta = \pi$, which described a half-wave plate. Two half-wave plates in series thus recover the original circular polarisation but change the signs of the amplitudes according to equation (16). The remainder of the theory proceeds as before and we can construct the analogue of the transfer matrix in equation (1) with β replaced by $-\delta$ and B by $B e^{i\Delta/2}$.

The observability of the photon amplitudes has no relevance here as we are concerned solely with observations on the Stokes operators¹² which characterise the polarisation properties of the beam and are quadratic in these amplitudes. The Stokes operators satisfy the same commutation rules as angular momenta and in view of the homomorphism of the group SU(2) on the group R3 any unitary transformation on a two

state system such as the photon has an analogous rotation for a spin $\frac{1}{2}$ fermion⁵. This justifies the photon analogue proposed above which is exact, provided the cycle of unitary transformations on the spin states of the photon is not interpreted as a rotation in real space. One can construct another photon analogue by using an optically active crystal to introduce a phase difference of 2π between the amplitudes $a_{\pm}$; in this case a real rotation of the plane of polarisation does take place but it is a rotation through an angle π rather than through an angle 2π (ref 4).

To observe the minimum in the optical interference pattern obtained by introducing a full wave plate in one arm of an interferometer it would be necessary to eliminate the phase factor $e^{i\Delta/2}$ in equation (16) by equalising the optical paths in both arms using a compensator according to normal optical practice. Two half wave plates in series with their optic axes at right angles would fulfil this role ideally. This requirement does not invalidate the principle of the device and indeed the same

defect exists in the neutron experiment (the 'residual λ shifts'³) although in a less severe form because the equivalent 'optical path difference' vanishes to first order provided the neutron energy is sufficiently low.

Mass mortality of photosynthetic bacteria as a mechanism for dark lamina formation in sediments of the Black Sea

M. Dickman

Department of Biological Sciences, Brock University, St Catharines, Ontario, Canada

I. Artuz

Hydrobiological Research Institute, Pollution Research Section, R. Hissar, Turkey

Black Sea seasonal entrainment of dissolved oxygen below the chemocline results in a temporary hiatus in which an oxygen induced mass mortality of photosynthetic bacteria initiates their mass sedimentation. During their sedimentation black coloured FeS-rich granules form. The abundance of these granules in the sediments dictates their colour and microlamination pattern.

RHYTHMICALLY laminated sediments from meromictic lakes and seas have long fascinated geologists, limnologists and oceanographers as these lamina have been used to construct detailed chronologies based on the supposition that a light and dark coloured band (couplet) represents events which repeated themselves on an annual basis.

Most of the sediments of the Black Sea are microlaminated¹ and these microlamina are thought to represent annual events or varves². On this basis a detailed chronology has been erected for the sediments of the Black Sea^{3,4}. Discrepancies between the ¹⁴C age and the varve count age for some of the recent Black Sea sediments¹ prompted us to examine these same sediments. An hypothesis concerning a mechanism for varve formation was formulated to explain the relative lack of correlation between the ¹⁴C and varve count chronologies in these microlaminated coccolith-rich sediments.

Recent reports⁵ have speculated that during both Cambrian and Precambrian times the majority of the oceans and seas of the world were meromictic, that is, permanently stratified into a deep non-mixing anaerobic layer termed the monimolimnion, and an overlying oxygenated mixing layer termed the mixolimnion. These conditions are similar to those currently found in the meromictic Black Sea⁶. To this extent the Black Sea

serves as a 'living fossil' and an understanding of the conditions responsible for dark and light coloured lamina formation there should assist us in interpreting the microlaminated deposits in the sediments of Cambrian and Precambrian seas.

The Black Sea is the largest 'lake' in the world⁶. The history of its tectonically formed euxinic basin, which now contains essentially marine waters, has included long periods when the basin was occupied by relatively fresh water⁷. We have therefore adopted the terminology of Hutchinson⁶ in describing this meromictic body of water. The water masses of the present day Black Sea are divided by a sulphide-rich chemocline into a lower saline anaerobic zone (monimolimnion) and an overlying less saline seasonally stratified mixolimnion.

During the last thousand years, a carbonate-rich microlaminated coccolith ooze has been deposited in anaerobic conditions at depths of 200 m or more along the bottom of the Black Sea^{1,2}. The detailed chronology of the Black Sea sediments discussed above was first formulated in the early thirties and forties^{3,4}. Many sediment studies of the Black Sea have been carried out⁷ since then but none have hinted at the possible impact of a mass mortality of photosynthetic bacteria on the microlamination pattern within its sediments. These bacteria are one of the main primary producers within the Black Sea⁸ and their annual mass mortality was not suspected until it was observed in another much smaller meromictic body of water in Quebec, Canada⁹.

The present study attempts to prove that oxygen-induced mass mortality of these photosynthetic bacteria (which are restricted to the anaerobic waters below 160 m)¹⁰ has been a major factor contributing to dark lamina formation in the Black Sea. Information is presented to show that the seasonal mass mortality of these photosynthetic bacteria occurs as a result of oxygen entrainment into the anaerobic waters which they occupy and that this deep-layer oxygenation is most likely

to occur during winter when partial destratification of the mixolimnion has occurred.

After the photosynthetic bacteria are killed by the addition of dissolved oxygen to their environment, they begin to settle slowly (1–2 m h⁻¹)¹¹ towards the bottom. During their descent the elemental sulphur which they store as a waste product of their H₂S-based photosynthesis¹² is exposed to the ferrous-rich waters of the upper layers of the anaerobic zone¹⁰. The elemental sulphur once exposed is capable of acting as nuclei for the formation of black ferrous sulphide compounds. The presence of ferrous sulphides and their products (such as FeS₂ pyrite) produces dark-coloured microlaminae.

Experimental methods

Using a Simrad SK3 sonar unit deployed in the Turkish hydrobiology research vessel, R/S Arar, it was possible to detect and later sample the thermocline and chemocline at 29° 05' E, 41° 40' N at a depth of 830 m, 30 km from the Bosphorus sill near Kilyos, Turkey (station A). Nansen bottles and a 10-l stainless steel Petersen styled closing cylinder were

used to remove replicated water samples for immediate preservation and later bacteriological analysis. A simple Van Dorn sampler replaced the more sophisticated equipment mentioned above at the Trabzon, Turkey Station (39° 55' E, 41° 10' N) which was located in 800 m of water (station B).

Quantitative estimates of algal and bacterial densities were made using a Fein Optik haemocytometer and a Leitz Orthoplan microscope. The plankton from immediately above and below the H₂S chemocline (160 m at station A, and 200 m at station B) was preserved with Lugol's IKI solution and concentrated by simple sedimentation¹³. Salinity, specific conductivity and temperature were measured at station B using a Beckman R-55-3 electrodeless salinometer. Dissolved oxygen was estimated at the same station using a Winkler calibrated Wissenschaftlich-Technisch Werkstätten Oxidigi Meter (model 5500). Such equipment was not available in Trabzon.

Sediments from the Black Sea sampled during the Glomar Challenger deep sea drilling operation² were available for study. Black Sea sediments were analysed by scanning electron microscopy: samples were freeze fractured, affixed to SEM

stubs and gold coated. Light- and dark-banded material from individual microlaminae was removed using fine dissecting forceps under a dissecting microscope to ensure that the material was not contaminated by adjacent lamina.

To determine the abundance (density) of dark coloured granules in the light and dark microlaminae, the previously isolated sediments were dried for 24 h at 80 °C and weighed after cooling. A sample of 0.1 mg from each of five light coloured lamina and five dark coloured lamina was suspended in 1.0 ml distilled water and a 0.1 ml aliquot of the homogenate was placed on an haemocytometer. The number of black granules were recorded for each of 40 randomly selected haemocytometer fields. A similar technique was used to determine the density of the photosynthetic bacteria from the IKI preserved water samples from the Black Sea.

Vertical distribution of photosynthetic bacteria in the Black Sea

As photosynthetic bacteria are light dependent, they develop population maxima at the minimal distance from the surface at which sulphide is available to them¹². In the Black Sea, sulphide is unavailable above a depth of 150 m at most locations¹⁴. Furthermore, these photosynthetic bacteria are killed by minute concentrations of oxygen¹⁵. The water column of the Black Sea is rarely anaerobic above a depth of 150 m (ref. 14).

On 31 October 1977 the photosynthetic bacteria were found concentrated at a depth of 200 m at the Kilyos station in the Black Sea (Table 1). Micrographs of these bacteria (Fig. 1a) indicated that the dominant form possessed an external morphology similar to that described by Buchanan and Gibbons¹⁵ for the photosynthetic bacterium *Thiocapsa roseopersicina* (spherical with a mean diameter of 1.5–2 µm). Many of our samples seem to contain blue-green algae as well as several other types of photosynthetic bacteria which we have yet to identify.

Individuals of *T. roseopersicina* in samples which were inadvertently exposed to small amounts of oxygen before preservation were often surrounded by a slime-filled envelope which may have caused them to aggregate into clumps (Fig. 1b). Irregularities in cell shape (Fig. 1a) were ascribed to the internal storage of elemental sulphur which this species produces photosynthetically as a waste product during the oxidation of H_2S ^{12,15}.

Photosynthetic bacteria taken from the other end of the Black Sea near Trabzon, Turkey on 17 November 1977 were similar to those at Station B but were concentrated at a slightly shallower depth (160 compared with 200 m) (Table 1).

Comparing our autumn photosynthetic bacterial densities with the winter densities reported by Kriss¹⁶ (for his Yalta-Batumi stations) it was evident that his February photosynthetic bacteria maximum was located at a much greater depth than ours. By late February the water at Kriss's winter stations was oxygenated to a depth of 300 m and the photosynthetic bacteria were concentrated at a depth of 500 m, indicating that oxygen might have been entrained down to that depth some time earlier or alternatively that the high bacterial densities which he observed at 500 m and deeper, may have included large numbers of dead bacteria which were settling out. Kriss's winter observations suggested that Black Sea waters below 200 m might be seasonally exposed to dissolved oxygen.

Grasshoff calculated that 500 km³ of surface waters containing an estimated 5×10^6 metric tons of oxygen penetrates the chemocline of the Black Sea each year¹⁴. Furthermore, Brewer *et al.*¹⁷ observed elemental sulphur as well as manganese and iron oxide granules in the anaerobic surficial sediments of the Black Sea along the Turkish (Anatolian) coast in 1,000 to 2,000 m of water. They interpreted this to mean that oxygen-rich surface waters had contacted the sulphide, manganese and iron-rich waters at and below the anaerobic chemocline in the Black Sea¹⁰ oxidising these waters and thereby precipitating elemental sulphur, iron and manganese oxides.¹⁷

Fig. 1 a–c, SEM photographs. a, *Thiocapsa roseopersicina* from a depth of 160 m at the Trabzon, Turkey station. Irregularities in cell surface may be the result of the internal storage of elemental sulphur¹⁵. Background specks are crystals caused by the evaporation of Lugol's¹³ IKI preservative in which the original samples were stored. Scale bar, 2 µm. b, A colony of *T. roseopersicina* from 160 m at the Trabzon station which had been inadvertently exposed to dissolved oxygen before preservation. Cells are bound together by thick mucillagenous secretions. Scale bar, 10 µm. c, A pyrite (FeS_2) framboid from a black microlamina at 4 cm depth in a sediment core from the Glomar Challenger station 381 (ref. 5). Scale bar, 2 µm. d, A transmitted light microscope photograph of a pyrite granule from a depth of 260 m in the Black Sea near Kilyos, Turkey. Although its framboid structure was later verified using SEM, its possible resuspension cannot be ruled out. Scale bar, 5 µm.

Vertical mixing of oxygenated surface waters to depths of 300 m or more in the Black Sea seems to occur in winter when the surface waters have been cooled and the water column approaches homeothermy. In addition, increased surface salinity before late winter rains reduces the amplitude of the vertical salinity gradient¹⁸. It is not surprising, therefore, that Kriss¹⁶ observed dead photosynthetic bacteria in well oxygenated water above 100 m after heavy winter storm activity presumably swept them up from the chemocline.

These four lines of evidence from independent studies all indicate that a seasonal mass mortality of photosynthetic bacteria is the result of partial and temporary oxygenation of the upper anaerobic layers of the Black Sea in winter.

Figure 2 provides a schematic representation of these events. In the uppermost diagram, six zones are represented by the letters A–E. These symbols depict the following portions of the Black Sea's water column: (A) the warm-water upper mixolimnion; (B) the metalimnion, upper and lower boundaries of which are represented by the dashed lines; (C) the oxygenated cold-water portion of the mixolimnion; (D) the anaerobic portion of the mixolimnion; and (E) the permanently anaerobic monimolimnion. The 'dots' concentrated along the top of the anaerobic mixolimnion (zone D) represent the photosynthetic bacterial plate.

During winter (central diagram) the metalimnion disappears as the thermal gradient (not shown) becomes less intense as surface temperatures decrease¹⁸. Except for a relatively few photosynthetic bacteria (which secrete sufficient slime to form a bacterial mass (Fig. 1b) which is enough to prevent dissolved oxygen from reaching the core before the bacterial mass has settled into deeper anaerobic waters) the intrusion of oxygen into the previously anaerobic portion of the mixolimnion (zone D) results in the mass mortality of all the anaerobic bacteria in this zone. Subsequently, these dead bacteria settle towards the bottom of the Black Sea at a rate of between 1 and 2 m h⁻¹ (ref.

Fig. 2 Schematic representation of the major seasonal changes in the vertical distribution of planktonic photosynthetic bacteria in the Black Sea with insets depicting the formation of light and dark microlaminae (see text).

11). During their descent they serve as nuclei for the formation of black FeS-rich compounds. Many of these compounds later form raspberry shaped pyrites (FeS_2) called 'framboids' (Fig. 1c, d).

The bottom diagram in Fig. 2 depicts the water column of the Black Sea in early spring when the majority of the mixolimnion is still oxygen rich. As spring and summer pass, decaying organic matter (tripton) from the overlying water accumulates on or near the chemocline where its continued decomposition removes any dissolved oxygen from the overlying water mass. This process increases the thickness of the anaerobic region of the mixolimnion (zone D). This in turn permits the photosynthetic bacteria to move closer to the surface where light intensities are higher¹⁹. By early winter, most of the subthermocline mixolimnion has been deoxygenated and a condition similar to that depicted in the uppermost diagram of Fig. 2 exists. The process previously described then repeats itself if winds of sufficient intensity to mix oxygenated surface waters to the depth of the photosynthetic bacterial plate reoccur.

Dark lamina formation

Metal sulphides such as FeS are extremely insoluble in neutral or alkaline water such as that found in the Black Sea²⁰ ($\text{pH } 7.5 \pm 0.2$)²¹. Thus HS^- in the presence of ferrous ions will form FeS compounds which give anaerobic sediments their characteristic black colour²². However, the exact nature of the compounds that form is dependent on the presence and concentration of a number of additional species in solution such as carbonates, silicates and heavy metals²⁰.

In the conditions observed in the Black Sea (alkalinity 4.4 meq l^{-1} (ref. 21); H_2S (HS^-) concentration of $300\text{--}350 \mu\text{g-atom l}^{-1}$ (ref. 21); a temperature 7 and 9°C ¹⁸; salinity of 22 ppt ¹⁰; and depending upon the depth of water, pressure of up to 200 atm) the precipitation of iron monosulfides would be

expected to occur at a ferrous iron concentration of roughly $4 \times 10^{-7} \text{ mol l}^{-1}$ (ref. 20). Only the sulphide-rich chemocline in the Black Sea contains such high ferrous iron concentrations¹⁴. Iron sulphide granules have been previously described for the sediments of the Black Sea^{5,22}. The general consensus seems to be that some of these black granules such as the pyrites may form during early diagenesis²³ however, Degens² described these same framboids in water samples taken several hundred metres above the sediment-water interphase in the Black Sea. These observations suggest that framboid formation begins in the water column following the mass mortality of photosynthetic bacteria. Since most of the Black Sea Basin is $1,000 \text{ m}$ or more in depth these bacteria would not reach the bottom for nearly 50 d given a sedimentation rate of $1\text{--}2 \text{ m h}^{-1}$. Thus it may be possible for their mineralisation and subsequent pyritisation to occur during their descent.

Data presented in Table 2 indicate that when black granule densities exceed about 1×10^6 per μg dry wt of sediment, a dark layer can be expected to form in the recent (coccolith-rich) sediments of the Black Sea.

The term black granule has been used above to indicate any opaque mass viewed with transmitted light microscopy. We are currently working (with S. Haynes) to determine the chemical composition of these iron- and sulphur-rich black granules. Several polished plastic impregnated cross-sections from the microlaminated Black Sea surficial sediments ($0\text{--}34 \text{ cm}$) have been produced. Pyrite framboid concentrations in these polished sections were 2 to 3 times higher in the dark coloured microlamina than in the light coloured ones.

Our studies and those of others^{8,16} have indicated a massive accumulation of photosynthetic bacteria just below the sulphide-rich chemocline in the Black Sea. These obligate anaerobic bacteria are instantly killed by the introduction of dissolved oxygen into their immediate environment.⁹ Following winter storm activity, large numbers of these photosynthetic bacteria have been observed in the surface waters of the Black Sea,¹⁶ indicating that vertical mixing had taken place.

The death of the photosynthetic bacteria on exposure to dissolved oxygen results in their gradual mineralisation as they sink slowly towards the bottom. During this process of mineralisation, these sulphur-filled bacteria act as nuclei for ferrous sulphide framboid formation. These framboids enter the bottom sediments of the Black Sea along with other sedimenting particles such as diatoms, coccoliths and clastics. Depending on the final black granule density and the degree of 'whiteness' of the underlying layer, a dark microlamina may form as shown inset in Fig. 2. However, if storm events during any particular winter fail to generate winds capable of oxygenating the chemocline, bacterial mass mortality there will fail to occur. As a result, a dark-coloured microlamina may fail to form. Discrepancies between 'varve' count and ^{14}C chronologies in recent Black Sea sediments may in part be related to this phenomenon.

The history of the oceans is in part the story of the progressive oxidation of their primordial anoxic environment²³. Degens and Stoffers⁵ have related the evolution of the oceans to the recent history of the present-day stratified waters of the Black Sea. The sediments of this curious body of water bear a striking resemblance to those deposited during Cambrian and Precambrian times in the bottom of some of the then existent world oceans⁵.

Data presented here indicate that dark lamina formation in this meromictic body of water is intimately associated with the mass mortality and subsequent mineralisation of the sulphur-rich photosynthetic bacteria which colonise the chemocline in the Black Sea.

We thank Drs Muzaffer Demir, Necla Demir, C. Karadeniz and A. Sengün for assistance, Dr Egon Degens (Hamburg University) and staff of the Doherty-Lamant Geology Laboratory for Glomar Challenger samples, and Howard Melville for help in electron microscopy.

letters to nature

High energy X-ray spectrum of Her X-1

OBSERVATIONS of Her X-1 taken during the on-state of its 35-d cycle¹ between 31 August and 12 September 1977 with the high-energy X-ray detector on board OSO 8 are reported here. A detailed analysis of the time-variable background spectrum suggests that the line features observed in our uncorrected time-averaged spectrum and those previously reported at 25, 60 and 135 keV can be caused by a $\sim 1\%$ change in detector gain. After correcting for this effect, a $3\text{-}\sigma$ upper limit of 4×10^{-3} photons $\text{cm}^{-2} \text{s}^{-1}$ is obtained on the line flux at 60 keV in the time-averaged spectrum, a flux significantly lower than that observed by Coe *et al.*² 6 months earlier. A $3\text{-}\sigma$ upper limit of 2×10^{-3} photon $\text{cm}^{-2} \text{s}^{-1}$ obtained for our pulsed spectrum at the same energy is higher than, and hence consistent with, the positive result reported by Trümper^{3,4} from a balloon flight during the same time interval.

The discovery by Trümper *et al.*^{5,6} of two strong lines in the pulsed X-ray spectrum of Her X-1 has inspired many other groups to search for this phenomenon. The stronger of the two lines, at 58 ± 5 keV, has now been observed by Trümper *et al.* on two separate balloon flights, one in May 1976⁵⁻⁷ and the second in September 1977^{3,4}. The second line, at an energy of approximately 110 keV, was observed in 1976 at the 2.2σ level, but in 1977 the line flux had decreased to below the detection sensitivity⁴. The measured absolute flux values for the two lines are given in Table 1. The credibility of these results is greatly enhanced by the observation that the flux in the lines pulses with the same 1.24-s period measured at lower energies. The time-averaged source spectrum can be distorted by systematic variations in the background spectrum or in the detector response. Because such variations are unlikely to occur with the same period as the observed pulsations from Her X-1, the use of the pulsed spectrum should eliminate these systematic effects.

No observation of Her X-1 by any other group has had the combination of sensitivity, energy resolution and time resolution necessary to positively detect and resolve either of these two lines. The reported line fluxes obtained by other groups at various different energies are given in Table 1. Unless otherwise indicated, the tabulated values are the line fluxes averaged over the 1.24-s period, or they are $3\text{-}\sigma$ upper limits. The standard deviation in the line fluxes are quoted directly from the respective authors and, in general, include the uncertainties in line width and instrument response function in addition to the statistical uncertainties. None of these reported line fluxes is

greater than 2.5σ although the statistical significance of the raw data of Coe *et al.*² is somewhat higher than this. Such a significance level is, however, reduced if the possibility of a line feature at any other energy is considered⁸. Recent results from the high-energy X-ray detector on HEAO 1 indicate a pulsed excess above the extrapolated low-energy spectrum consistent with the 1977 flux observed by Trümper *et al.* in the 58-keV line¹⁰.

The observations reported here were made with the high-energy X-ray detector on OSO 8, which is described in detail elsewhere¹¹. The instrument is an actively shielded CsI(Na) scintillation detector with a sensitive area of 27.5 cm^2 and a circular field of view with a full width at half maximum (FWHM) of 5° . The timing resolution is 0.3125 ms for each recorded photon, and the energy resolution is $\sim 25 \text{ keV}$ (FWHM) at

Fig. 1 The calculated counting rate spectrum of Her X-1 determined for the total observing time from 31 August to 12 September 1977. The counting rate is plotted on a linear scale to show the negative calculated fluxes at 45 keV, 70–100 keV, and $>170 \text{ keV}$ and also the apparent line features centred at $\sim 60 \text{ keV}$ and $\sim 135 \text{ keV}$.

60 keV. The instrument is mounted in the rotating wheel section of OSO 8 with its field of view offset from the anti-spin axis by 5°. During the Her X-1 observations, the anti-spin axis of the spacecraft was orientated at an angle of $(5 \pm 0.5)^\circ$ from the direction to the source thus causing a modulation of the source signal for each wheel rotation. Our method of analysis uses this 10-s modulation to determine an accurate time-averaged source spectrum in the presence of the rather large and variable detector background¹². The pulsed spectrum is determined by combining the on-source data modulo the source period taken from Pravdo *et al.*¹³. The photon detection times are first adjusted for the time-of-flight variations between the source and the satellite.

The time-averaged spectrum obtained from all of our Her X-1 data shown in Fig. 1 contains two significant line features, one at ~60 keV and the other at ~135 keV. These features are not evident, however, in the pulsed spectrum. Furthermore, the

calculated source fluxes at 45 keV, 80 keV and >180 keV were found to be negative. We now believe that the apparent line features and the negative source fluxes are all caused by a small change in the gain of the photomultipliers at each wheel rotation. Such a change in gain, of the order of 1% or less, can result from the changing orientation of the photomultipliers (RCA 31016F) in the Earth's magnetic field. A cylinder of 4-mil CO-NETIC magnetic shielding (Perfection Mica Co.) was put around each photomultiplier, but a residual variation of gain with magnetic field remains. This is presumably because it was not possible to extend the magnetic shield one diameter beyond the photocathode as recommended by RCA. The effect of such a change in gain on the detector counting rate depends on the shape of the background spectrum. Our background spectrum is shown in Fig. 2 together with the difference between two background spectra measured with a gain difference of 1%. Such a difference spectrum is the apparent source spectrum which would be calculated in the absence of any real source. The line features and the negative source strengths in the time-averaged Her X-1 spectrum clearly match this difference spectrum both in energy and in the relative amplitudes of the peaks and valleys. The possibility⁸ of a third positive feature at 25 keV is interesting although, in our measurements, such an excess is lost in the statistics of the real source flux at that energy.

Assuming that a small gain change accounts for the features in the source spectrum, it is easy to compute the true time-averaged spectrum. This is possible in spite of the complicated variations in the strength and direction of the Earth's magnetic field seen by the photomultipliers as the satellite moves in its orbit. The shift in background spectrum resulting from the gain change at each wheel rotation always results in an apparent source spectrum equal to the difference spectrum shown in Fig. 2 multiplied by some factor which can be either positive or negative. This is true only when the shape of the background spectrum remains constant. This is satisfied to the required accuracy using only data collected well out of the South Atlantic Anomaly. The true source spectrum is determined by subtracting the background difference spectrum, for some mean value of the gain change, from the calculated source spectrum. The mean value of the gain change can be most easily determined by a least-squares technique in which the assumed gain change is adjusted until the calculated source strengths in all energy bins are positive or zero to within the statistical uncertainties. The time-averaged spectrum obtained in this way and unfolded through the detector response function using the methods of Dolan *et al.*¹² is shown in Fig. 3. Only data from the non-eclipsed parts of the four binary periods during which the source flux was

Fig. 2 a, Detector background spectrum for the Her X-1 observing time. b, The difference ($\times 25$) between two background spectra measured with a gain difference of 1%.

highest (31 August–6 September 1977) were used to obtain this spectrum. No significant features are evident above the 3σ levels given in Table 1. Positive detection of the pulsed flux was made up to an energy of 33 keV and no significant features are observed in the pulsed spectrum above the 3σ upper limits given in Table 1.

An understanding of features observed in our time-averaged spectrum of Her X-1 has been demonstrated in terms of small changes in gain of our X-ray detector. Such changes in gain can produce apparent line features in the spectrum at energies which have previously been reported in the literature. Brecher and Ulmer⁸ have pointed out the probable relationship to the detector background of the 1.5σ feature at 25 keV in the OSO 7 spectrum of Her X-1. Durouchoux *et al.*⁹ have shown that a small change in gain can explain the apparent line features at 57.5 and 137.5 keV in their time-averaged Her X-1 spectrum obtained on a balloon flight in May 1975. Coe *et al.*² report a line feature at 64 ± 6 keV in the time-averaged Her X-1 spectrum

from the high-energy X-ray detector on Ariel V. Attempts to explain their result in terms of a gain change have not been successful because the detector background spectrum does not have the required shape¹⁴.

The upper limits on the line features in our pulsed spectrum of Her X-1 are consistent with the results of Trümper *et al.*³⁻⁷. They do show that the line features are not significantly stronger when averaged over a full binary period as compared to the flux measured during a relatively short balloon flight. Finally, it must be emphasised that the reported line at 58 keV remains highly credible in view of its pulsed nature. Confirmation by different observers and measurements with improved energy resolution to determine the true line width remain highly desirable objectives.

We thank Roger Thomas, the OSO Project Scientist, for his efforts in making this long observation of Her X-1 possible, and Steve Pravdo for supplying us with the observational parameters of the pulsations. G.S.M. was supported by NASA grant NSG 5066 and E.P.C. by contract NAS5-24451.

Physical reality of shot noise model for the short-term variability of Cyg X-1

TERRELL¹ pointed out that the rapid intensity variation of Cyg X-1, first discovered in Uhuru observations², was well simulated by shot noise, that is, random superposition of shot pulses of constant shape ($\Sigma h(t-t_i)$; t_i is a random variable). Since then this model has become widely accepted and used to summarise the observational data³⁻⁷ which suggest the physical process of overlapping bursts of X-ray emission from local hot spots in an accretion disk around a black hole. The variability characteristics of shot noise are roughly determined by two parameters⁸, shot rate λ and effective pulse length τ_{eff} of a single shot $h(t)$. Almost all the observational data so far

obtained seem to be consistent with shot noise having a pulse length of a fraction of a second—although shot rate varies from one observation to another—which is thought to support the validity of the model. This letter points out that shot noise is only an example—and a rather artificial one—of a random process which can explain the basic observed properties of the variation (its correlation time and magnitude) and why it does not need to be singled out among many types of possible stochastic processes. Therefore, physical interpretation of the observation strictly based on the shot noise parameters may be misleading.

First note that a stochastic time series $x(t)$ is described by a set of statistics—the first order one $\langle x(t) \rangle$ (average), the second order one $\langle x(t_i)x(t_j) \rangle$ (variance and autocorrelation), the third order one $\langle x(t_i)x(t_j)x(t_k) \rangle$ and so on. A major concern in shot noise analyses has been to estimate the two parameters τ_{eff} and λ from observational data. Note, however, that shot noise can be completely assimilated to observational data by adjusting $h(t)$ so that its autocorrelation equals that of the data. The shot rate λ is a scaling factor for the magnitude of variation. The shot noise generated this way gives a complete simulation of the data up to the second order statistics. In other words, for any given time series a shot noise can always be generated so that there is no way to distinguish them within the second order statistics.

Such an all-inclusive nature of shot noise obscures the physical meaning of the shot noise parameters, especially λ if τ_{eff} has model-independent meaning of a characteristic time scale. Its applicability to data does not prove the physical reality that X rays are indeed emitted in pulses with shot rate λ , without other additional supporting facts, observational or theoretical. Shot noise was originally introduced to explain and analyse the fluctuation of electric current in vacuum tubes, which is justified because it is essentially a quantum effect: with Cyg X-1 there is no such justification.

Sutherland *et al.*⁹ have discussed an extended shot noise model in which steady component was taken into account, introducing another parameter, 'shot noise fraction' f . This discussion shows that λ and f cannot be uniquely determined by the second order statistics, and, in fact, the third moment $\langle x^3(t) \rangle$ was used to estimate the parameters. The analysis not only involves the third moment whose estimation error can be rather large, but also depends on the assumed shape of $h(t)$.

The usefulness of such an analysis is examined in the following example. One of the most basic and physically important stochastic processes, is brownian motion, its simplest model is described by Langevin equation¹⁰,

$$\frac{du}{dt} = -\gamma u + R(t)/m$$

where u and m are velocity and mass of a brownian particle respectively, γ is coefficient of friction, and R is random force acting on the particle which can usually be considered to have a white spectrum (infinitesimal correlation time). The resulting stochastic time series $u(t)$ may be similar, in a generalised sense, to shot noise; fluctuations of u are generated by R and decay with $1/\gamma$, that is $h(t) = h \exp(-\gamma t)$ except that h in this case is not a constant but follows Maxwellian distribution law. It is possible to apply the extended shot noise model forcibly to $u(t)$, but the best fit parameters λ and f will hardly have any physical meaning, and indicate still less the collision rate with surrounding particles and 'shot fraction'. Should we try to apply the model introducing still higher moments to deduce the distribution parameters of h ? The physically relevant part in this example is the correlation time $1/\gamma$ of the fluctuation and the magnitude of variance $\langle u^2(t) \rangle$ which is equal to kT/m (equipartition law), and higher order statistics are of secondary importance.

As illustrated by the above example (and relaxation and fluctuation theories in statistical physics), physical understand-

ing of variation should be sought from the second order statistics, before getting too deeply involved in a rigid model based on *ad hoc* assumptions. Assuming shot noise with $h(t)$ and λ defines the complete set of statistics (or the probability density) which is practically beyond observational tests. Whether variation is shot noise or gaussian noise or any other type of fluctuation does not affect the second order statistics; physical discussion is possible without such a specification.

Finally, there are observational indications in Cyg X-1 which do not favour the simple shot-noise view of overlapping unit bursts. Ogawara *et al.*¹¹ noted the energy dependence of the variation of the rocket data in the 1.5–25 keV range and discussed the compatibility with the shot-noise view. Recently I carried out a balloon observation¹² of the short-term ($\sim$ s) variability in the hard (≥ 20 keV) X-ray region with a large-area detector, to obtain an integral, wide-band picture of the variation. These results, together with those of the former rocket observation¹¹, suggest that the variation is essentially spectral, keeping the total X-ray luminosity relatively constant, although a narrow band observation indicates intensity variation. A possible model of such a variation based on the inverse-Compton emission from a two-temperature disc around a black hole^{13,14} was suggested, which may exemplify a physical discussion noncommittal to the higher order statistics. The detail of the observation and discussion will be published elsewhere.

I thank Professors M. Oda, S. Miyamoto and Y. Ogawara for useful discussions.

The spectrum of the supernova in MCG43223

A POSSIBLE SUPERNOVA in the galaxy MCG43223 was found by Gilmore¹ on 8 May 1978. The complex emission and absorption features of its spectrum which we have recorded are described below. Our findings confirm that this object is a supernova of Type V.

Gilmore reported that, at the time of discovery, the object was ~ 17.5 mag and that it was not visible on plates taken on 8 March and 8 April. Its presence was confirmed² by taking a plate of the galaxy on 25 May using the UK 1.2 m Schmidt telescope, Siding

Fig. 1 Galaxy MCG43223: *a*, 60-min exposure on IIIaJ/GG395 filter 28 June 1976; *b*, 15-min exposure on IIIaJ/GG395 filter 25 May 1978. The scale is shown by the bar which is 20 arc s in length. North is at the top and east to the right.

Fig. 2 The spectrum of the supernova in MCG43223: N/S refers to incomplete subtraction of the 5,577 Å night skyline.

Spring. The object's position was determined² to be RA = 13 h 27 min 32.60 s, dec = -21° 29' 24.0" (1950), being located 15 arc s due west of the galaxy's nucleus. Its photographic magnitude was estimated to be 20.0. A print taken from the UK Schmidt plate is shown in Fig. 1 where it is compared with a prediscovery photograph. Inspection of the print indicates that the object seems to be situated in a spiral arm of MCG43223. K.H.E. and J.C.B. obtained a spectrum of this object on 29 May with the Boller and Chivens spectrograph and Robinson Wampler³ image dissector scanner at the $f/15$ focus of the 3.9 m Anglo-Australian Telescope, Siding Spring. The spectrograph gave a nominal dispersion of 200 Å mm^{-1} , and a slit width of 2 arc s was used which corresponded to a final spectral resolution of $\sim 10 \text{ Å}$. The spectrum, which has been corrected for non-uniformity of the detector but not for its spectral response, is presented in Fig. 2. Bad weather severely curtailed our intended programme; we were unable to obtain standard star spectra or a spectrum of the galaxy.

We believe this spectrum, which shows a complex mixture of emission and absorption features, confirms that the object is a supernova in MCG43223. We have identified five features in the spectrum with H I, namely the Balmer series from H α through

to H ϵ ; and we tentatively identify He I, C IV and Ca II. In addition the spectrum contains an absorption feature near $\lambda(\text{rest}) = 3,800 \text{ Å}$ which seems to be a common feature in supernovae spectra⁴.

Comparing our data with the spectra illustrated by Greenstein and Minkowski⁴, we identify the supernova as Type V (a subclass of Type II), as it shows many features in common with the Type II 1961 V in NGC1058⁴. This is the first time that a spectrum of a Type V has been recorded so close to maximum. However, there is some difficulty in making the comparison, as the published data for NGC1058 refer to a period ~ 173 d after maximum. For our data the spectrum must have been obtained between 21 and 50 d after maximum. A survey of plates taken of this field between 5 April 1978 and a month later should give a more exact timing of the maximum. The Balmer lines give $z = 0.012$. Equating this redshift with that of MCG43223 we obtain a distance of 65 Mpc, using $H = 55 \text{ km s}^{-1} \text{ Mpc}^{-1}$. With the estimated brightness of $V \sim 17$ we obtain $M_v = -17.1$ assuming no absorption, which is reasonable considering the high galactic latitude ($b = 40^\circ$). This absolute magnitude compares well with the accepted value for Type II supernovae,

$M_v = -17.54 \pm 0.26$ given by Tammann⁵. We intend carrying out further spectroscopy on the object, providing that it does not fade too quickly, to monitor spectral variations.

Search for the 1.2 MeV γ -ray line of Walraven and Haymes

WALRAVEN AND HAYMES¹ have reported the possible detection of a ~ 1.16 MeV γ -ray line at a flux level of $(3.4 \pm 1.5) \times 10^{-3}$ photons $\text{cm}^{-2} \text{s}^{-1}$ from a point in the galactic plane ($l = 345^\circ$, $b = 5^\circ$). If correct this could be an enormously important result constituting the first direct confirmation of theories of explosive nucleosynthesis (ref. 2 and refs therein). Clayton *et al.*^{3,4} have predicted that the most intense γ -ray line to be emitted from the radioactive debris of a typical supernova after ~ 3 yr will be the 1.156 MeV line from the decay of ^{44}Ti ($\tau_{1/2} = 48$ yr). However, the reported detection was at a marginal level of statistical significance (2.6σ). It was mainly the "remarkable double coincidence that just the theoretically-predicted spectral anomaly occurred" when the telescope was pointed at a region of the galactic plane believed to contain young supernova remnants, that encouraged these workers to report this result. Clearly an independent attempt to confirm this observation with a telescope of finer energy resolution is called for. Here we report the result of such an attempt. Our conclusion is that the reported positive detection was probably a statistical fluctuation.

A balloon-borne high-resolution (3.2 keV FWHM at 1.156 MeV) γ -ray telescope was flown on 11 November 1977 from Alice Springs, Australia. The instrument was essentially the same as that previously described^{5,6}, but an important modification made for this flight was the replacement of the central Ge(Li) detector with a large volume, $\sim 130 \text{ cm}^3$ high-purity germanium detector. This necessitated an increase of the effective entrance aperture in the 400 lb NaI anticoincidence shield to 16° FWHM at 1.156 MeV. The direction ($l = 345^\circ$, $b = 5^\circ$) was tracked for 1 h starting at 23.51 UT with the balloon at an atmospheric depth of 3.0 g cm^{-2} . The search for the 1.156 MeV line was terminated when our quick-look data revealed that no indication of the feature at the reported flux level was evident.

In Fig. 1 we show the sum of all our data in the vicinity of 1.16 MeV. Only corrections for drifts in the energy calibration with time have been made. No astrophysical γ -ray line is apparent in these data nor in any of our data within hundreds of keV of 1.156 MeV. These data can be used to set a 1.156 MeV γ -ray line flux limit. Using the known detector efficiency, instrumental dead time and atmospheric attenuation we find a

2σ limit of less than $2.8 \times 10^{-4} \sqrt{\text{width (in keV)}}$ photons $\text{cm}^{-2} \text{s}^{-1}$. Since the linewidth is expected to be ~ 40 keV (FWHM) (ref. 7) this corresponds to a 2σ limit of less than 1.8×10^{-3} photons $\text{cm}^{-2} \text{s}^{-1}$ which is a factor of two less than the reported intensity. Thus the reported positive detection seems likely to be a statistical fluctuation.

Does the troposphere respond to day-to-day changes in solar magnetic field?

WILCOX ET AL.¹ have reported a statistical correlation between the solar magnetic sector structure and the vorticity area index (VAI) during the period 1964–70. Characteristically, the VAI reached a minimum 1 day after the passage of a solar magnetic sector boundary (SSB), with the response being greatest in winter and at 500 and 300 mbar. This result has been the basis of many subsequent studies; in particular Wilcox *et al.*² strengthened their previous results by extending the period of analysis to the 11 year interval 1963–73. We have examined the period 1974–77 and find that this characteristic response is now no longer evident.

Williams has recently³ analysed the four components of the Lorenz energy cycle in an attempt to clarify the physical processes involved in the apparent solar modulation of the VAI. Although no statistically significant solar effects were discovered, some similarity was found in the behaviour of the eddy kinetic energy (KE) and the VAI. However, the KE exhibited a greater averaged response to the passage of an SSB (as obtained using a superposed epoch analysis) during the 1960s than the 1970s. Consequently, if there is a correlation between the KE and the VAI we might expect the effect of an SSB crossing on the VAI to also be weaker during the more recent years. This prompted us to extend the analysis to the period 1974–77 to determine whether or not the characteristic response of the VAI still existed during these years.

The VAI was calculated by the method described previously¹ using the National Meteorological Center data available at the National Center for Atmospheric Research. The VAI, at a particular pressure level, is defined to be that area of the Northern Hemisphere north of 20°N in which the absolute vorticity exceeds $24 \times 10^{-5} \text{ s}^{-1}$ plus that area in which it exceeds $20 \times 10^{-5} \text{ s}^{-1}$. This is a modification of the original index defined by Roberts and Olson⁴. In order to match the previous work, a superimposed epoch analysis was performed using the VAI and SSBs⁵ during the winter months 1 November–31 March. However, we required that all the VAI data be in this interval

Fig. 1 Energy spectra in the vicinity of 1.156 MeV. Raw data corrected only for drifts in the energy calibration. Each point represents a 1-keV wide energy bin.

Fig. 1 Results of superposed epoch analysis of VAI plotted against SSBs during the periods indicated. *n*, no of SSB's included. *a*, 500 mbar; *b*, 300 mbar.

whereas the criterion used by Wilcox *et al.*¹ was that all the SSBs be in it. Our requirement eliminates 11 key days used by Wilcox² and 1 during the interval 1974-77. In all other aspects our approach is identical to that of Wilcox *et al.*¹.

Figure 1*a* illustrates the results at 500 mbar. For the interval 1963-73 we obtained results consistent with those of previous authors. This satisfied us that we were using the same analysis techniques as had been used in the earlier studies. However, for the years 1974-77 (our analysis ended in March 1977 so that 3½ years are included) we find a response completely unlike that of the previous years. Similarly, at 300 mbar Fig. 1*b* shows that although the absolute minimum is still on day +1 the magnitude of this response, at best, is greatly reduced. We thus find evidence to support the hypothesis of a correlation between the VAI and the KE.

In order to interpret this result we sought differences between the two time intervals which might qualitatively explain our findings. First, although the new result is for a short time interval, the number of key dates analysed, 49, is comparable to the 54 first analysed between 1964-70. Second, it may be argued that the years 1974-77 spanned a solar minimum so that we may expect little solar effect on the weather. This hypothesis was tested by examining a similar 3½ year period, 1963-66, which covered the previous solar minimum. However, during these years the VAI clearly exhibited the characteristic response to the passage of the SSBs². It therefore seems unlikely that the new result was caused by a lack of solar activity. Third, since a superimposed epoch analysis is essentially a cross correlation

integral, the results depend on any periodicities in either dataset. Thus, in this study, any differences in the spectrum of separation of key dates would influence the results. However, no obvious differences are evident in the histograms of sector widths as shown in Fig. 2. Fourth, it is clear from Fig. 1 that the typical values of the VAI are much lower during the more recent years. This suggests the possibility that the atmosphere is not in a 'suitable state' to respond to a solar impulse when the VAI is low. Finally, there is the possibility that the years 1963-73 or 1974-77 are yielding an anomalous result. Neither of these possibilities may be discounted using the current database.

As this is a purely statistical study there is no method for conclusively proving which, if any, of the last three possibilities is the correct interpretation. However, since there are, at present, no workable physical mechanisms, it seems that the simplest interpretation is that the years 1963-73 yielded an anomalous result which was of unusually high statistical significance⁶ and which was self-consistent for an unusually long time. We therefore conclude that our work weakens the evidence for this particular sun-weather correlation.

Ordered arrangements of spheres of two different sizes in opal

GEM OPALS consist of a regularly ordered array of silica spheres of uniform size¹. Generally in any given gem stone the uniformity is maintained throughout the gem, although occasional samples contain bands in which the size varies from band to band. A sample of Brazilian gem opal of this banded type has now been found to contain a band in which there are spheres of two different sizes mixed together. Long-range ordering within this mixture has produced several different types of regular superstructures, which can be seen in section in electron micrographs of replicas of chips of this specimen (Fig. 1).

Packing arrangements of monodispersed spherical particles are of great general interest, and suspended latex spheres may order under the influence of electrostatic interaction from the surface double layers². Close-packed ordering also achieves a higher density than random packing, and it is generally conceded, but not proved, that a system of an infinite number of uniformly-sized spheres achieves its maximum density by regular close-packing³. The monodispersed spheres of silica in gem opal have been found to be packed in a close-packed manner⁴. Arrangements of mixtures of two sizes of sphere have been investigated experimentally⁵ and by computer simulation⁶ in order to determine packing densities, and to find out how the

Fig. 2 Histograms of width of sectors analysed in each period.

packing arrangement of one component is modified by the introduction of a second component of different size. No long-range ordering of the two components was observed in any of these cases, despite vibration of the arrays to simulate annealing⁵.

The regular arrangements of the two sizes of sphere in this unusual Brazilian sample were found in a number of replica fragments of a few chips from a single sample. The specimens used for electron microscopy were casually fractured, and so exposed surfaces of random orientation with respect to the array, with the orientation varying from fragment to fragment. The pieces of replica could not be related back to the original specimen. The appearance in an electron micrograph of a section through an array is expected to depend very much on the orientation of the section, but several different sections from this specimen could be recognised as coming from the same arrangement, and different ordered arrangements could be distinguished. Two approximate structures (to be described elsewhere) have been deduced from electron micrographs.

It appears that in this part of the opal there are just two sizes of sphere, with diameters of 0.18 and 0.1 μm respectively. In those places where ordering was observed it was most extensive, covering, for example, most of the area of a fragment of replica on a grid, for example, 1–2 mm. The different structural arrangements seem to be related to variations of the proportions of the two sizes of sphere in different places. Some places contained disordered mixtures of the two sizes, and in one place there was a boundary across which small spheres appeared to have penetrated into an array of larger ones. An example of part of the exposed surface of one of the ordered arrangements is shown in Fig. 1: it shows large spheres regularly dispersed among small ones, and close inspection shows that there is also a complex ordered arrangement of the small ones. How did the mixture of two sizes of spheres form and what was the driving force for long-range ordering?

It has been suggested⁷ that uniformity of sphere size in natural gem opal resulted from very slow, steady, near equilibrium conditions for the precipitation of silica from an underground solution. It is not clear what creates close-packing in the natural system. However, in laboratory experiments, monodispersed silica spheres settle quickly to a layer at the bottom of a vessel, and order (as shown by the formation of columnar grains exhibiting iridescence) increases over a period of months.

It seems likely that an understanding of the reasons for the ordering of the two sphere sizes found in the Brazilian sample might shed new light on the mechanism of opal formation. We have considered two possible mechanisms which could lead to ordering in the Brazilian sample. First, the two sizes of silica spheres might have formed concurrently and ordered whilst in

the colloidal state under the influence of long range double layer repulsions. This order could then be retained during sedimentation and compaction. Alternatively, ordering might have occurred solely under the influence of the Earth's gravitational field during compaction. This allows an alternative possibility of the two sphere sizes forming at different times and mixing by infiltration of the smaller spheres after an initial settling.

The first possibility is based on the knowledge that colloids consisting of spherical particles of equal size can order under the influence of repulsive double layer forces⁸. The question here arises as to what sort of ordering would be favoured by a colloid containing particles of two sizes. Would colloid theory predict a two-phase system with one phase containing small particles and the other phase containing large particles, or would a single mixed phase be preferred? A partial answer to this question has been obtained by considering pairwise potentials arising from van der Waals⁹ and double-layer forces¹⁰ between large spheres (U_{AA}), small spheres (U_{BB}), and mixed, large and small spheres (U_{AB}). For the simplest case of a system with equal numbers of small and large spheres we can simply regard the system as analogous to a binary alloy (see, for example, ref. 11). If then we find that $U_{AA} + U_{BB} > 2U_{AB}$, we conclude that a single mixed particle phase will result. Our calculations based on the observed sizes show that for systems with reasonably large double-layer interactions the above inequality is valid, down to a separation of the surfaces of the particles of about 50 Å, indicating that colloidal ordering could be responsible for the type of structures observed. As interparticle separations become less than 50 Å van der Waals forces become increasingly important and finally cause the particles to cohere strongly. At some later stage evaporation of the parent solution precipitates a final residue of silica which forms a cement and imparts additional strength to the opal. Gravity may play a part in compaction through sedimentation during opal formation in this model but is not essential to the ordering process.

The second ordering mechanism is one in which gravity is the controlling influence. One difficulty with the colloid model is in understanding how two quite distinct particle sizes could have been formed concurrently. In the gravity-controlled model we suppose that the smaller particles were formed after the larger ones, and penetrated into an already settled, but not yet compacted array of large spheres. Laboratory observations have confirmed that this process is possible for latex spheres¹². In these conditions sufficiently close contact would be maintained that pairwise interactions would be dominated by van der Waals forces. Our calculation shows that these forces alone do not favour the formation of a single phase, and therefore gravity must provide the ordering potential in this case. It follows that the stable system should be the one with the highest density. The density of the single phase would then be required to be higher than that of a close-packed monodispersed system, and this is certainly the case for one of the structures observed in Brazilian opal.

We conclude that it is not yet possible to determine which of the two suggested mechanisms of ordering occurs in the natural growth of opal. The fact that both major driving forces lead to a preferred AB (single phase) structure means that we are unable to use the two sphere size regions of the Brazilian gem to distinguish between the mechanisms. In nature both mechanisms may in fact operate. Their relative influences will depend on the precise physical and chemical characteristics of the parent solution, for example density, pH and ionic concentration.

Anisotropy of melting for cubic metals

KINETIC studies of superheating of metals^{1,2} have shown that surfaces play an important part in initiating melting. Recent work on the anisotropy of vapour pressure³ suggests a strong dependence of melting on crystallographic orientation. There are models of melting⁴⁻⁷ which indicate that surfaces may become disordered (that is, lose their long-range order) at temperatures below the bulk-melting point. These temperatures are characteristics of the crystallographic planes of a metal. Based on simple considerations, we attempt here to estimate the melting temperatures of major low-index planes for close-packed cubic metals. The results are discussed in terms of low-energy electron diffraction (LEED) study and current theories of melting.

On the basis of Lindemann's melting criterion⁵, one can express in terms of harmonic approximation the relation between Debye temperature θ_D , melting point T_M , atomic weight M and mean-square amplitude of atomic vibration $\langle u^2 \rangle$ as⁸

$$\theta_D^2 = C \langle u^2 \rangle^{-1} [T_M/M] \quad (1)$$

where C , a constant, is equal to $9\hbar^2/k_B$ with $\hbar$ denoting the reduced Planck's constant and k_B the Boltzmann's constant. It has been well established through both experimental measurements and theoretical calculations that $\langle u^2 \rangle$ is much larger at a surface than in the bulk⁹. Consequently, the degree of anharmonicity should be much greater at the surface than in the bulk. From the various methods of studying surface anharmonicity¹⁰, the simple force constant method, which is based on anharmonic perturbation theory, is used here. Only the normal component of mean-square displacement denoted by $\langle u_z^2 \rangle$ is considered, as it is this parameter which is generally greater than the tangential component. The ratio of this value for surface (S) and bulk (B) that is, $\langle u_z^2 \rangle_S / \langle u_z^2 \rangle_B$ for various crystallographic planes, is only known for close-packed cubic metals as 1.87, 1.83 and 1.86 for (100), (110) and (111) planes, respectively¹¹. An analysis of equation (1) in terms of surface and bulk components followed by rearrangement would give

$$T_{MS}(hkl) = [\langle u_z^2 \rangle_S / \langle u_z^2 \rangle_B] [\theta_{DS}(hkl) / \theta_{DB}]^2 T_{MB} \quad (2)$$

A subsequent estimation of $T_{MS}(hkl)$ for planes (hkl) is presented in Table 1 for metals for which the various parameters of equation (2) are known¹²⁻¹⁴.

The present results on $T_{MS}(hkl)$ are considered to be fairly reasonable. For example, the surface melting temperature for Pb, which varies from (111) to (110) planes over a range of 49 K, is comparable with the 40 K obtained from LEED studies⁷. It is, of course, evident from equation (2) that T_{MS} values would depend on the choice of the ratio $\langle u_z^2 \rangle_S / \langle u_z^2 \rangle_B$ and on the adequate calculation of surface Debye temperature $\theta_{DS}(hkl)$ which is primarily based on summation of Morse potentials¹².

It has been pointed out¹⁵ that Lindemann's melting hypothesis consistently predicts the absolute melting temperature too high. It is argued in terms of amplitude of vibration of surface atoms that the 'critical amplitude' (for melting) will be reached at the surface before the interior. This view has been confirmed by LEED results⁷ and molecular dynamics studies⁴. The results in Table 1, with T_{MB} being consistently higher than T_{MS} , therefore agree with the above concept. It is also evident from Table 1 that T_{MS} decreases from (111) to (110) planes. Such a trend

§Estimated using equation (2).

apparently indicates the dependence of melting point on the density of packing of atoms in a particular crystal plane. One can thus conclude that a maximum vibrational instability is associated with the least densely packed plane. This conclusion is consistent with the theories of melting^{5,16,17}. Following the work of Maradudin *et al.*⁹, one would expect the amplitude of atomic vibrations to be maximal for planes with the least atomic packing density. It is known that the Debye temperature is closely related to the amplitude of vibration. As a result, θ_{DS} is expected to be lower with less closely packed planes; this is apparent in Jackson's results¹². Because, according to Lindemann's criterion, the melting point of a metal is directly proportional to the Debye temperature (equation 1), the lowest melting point is expected for a plane with the lowest surface Debye temperature, that is, with least close packing of atoms, as indeed has been indicated in the present work. On the basis of the estimated values of Table 1, a satisfactory quantitative relation has been obtained between $T_{MS}(hkl)$ and work function of the single crystal faces of a bare metal possessing close-packed cubic structure¹⁸.

Superheated liquids containing suspended particles

THE superheat temperature limits of particle-free liquids have been previously investigated, notably by Skripov¹, Blander *et al.*², Apfel³ and Porteous⁴. Examinations of the homogeneous nucleation of liquid pentane have found the experimental limit of superheat temperature to be 146.5°C, which agrees well with the theoretical limit of superheat of 147.7°C calculated by Blander *et al.*² using the theories of Döring⁵, Volmer⁶ and Kagan⁷. Studies of superheating pure liquids have stressed the

Fig. 1 *a*, Alumina (0.06 μm), run 3-15A; *b*, sericite (50 μm), run 3-14AC; *c*, carbon black (0.47 μm), run 6-12A. Particles suspended in pentane.

importance of keeping the liquid phase scrupulously clean and noted that the presence of ‘motes’ and particles interfered with obtaining experimentally consistent results because these served as nucleation centres; however, we know of no previous explicit study on the effects of suspended particles. We now report that liquid pentane and pentane/chloroform mixtures containing suspended solid hydrophobic and hydrophilic particles (carbon black, alumina, sericite) have been superheated as high as 110°C above their normal boiling points, and to within 3°C of the theoretical homogeneous limit of superheat of the particle-free liquid. This is the highest degree of superheat ever reported for liquids in the presence of solids other than smooth glass capillaries.

We examined the superheating of liquid *n*-pentane containing various amounts of suspended carbon black (Cabot; MT-X25, 0.47 μm diameter, Sterling R, 0.075 μm), alumina (Rhode Island Abrasives, 0.05 μm) and the mineral sericite

[(OH)₂KAl₂(AlSi₃O₁₀)] (50 μm). We used a method of superheating liquids modified from that of Defour⁸, who superheated droplets of test liquid suspended in an immiscible, less volatile, host liquid, that acted as a ‘liquid skinned’ vessel, thereby avoiding contact with a solid container wall. We used a thermal gradient column modelled after those used by Moore⁹, Skripov¹⁰, Apfel³, Blander *et al.*² and Porteous⁴.

Pentane droplets (~1 mm diameter) were heated above their normal boiling point (36.1 °C) as they ascended slowly in a 47-mm i.d. glass column filled with ethylene glycol (host liquid), in which a vertical temperature gradient existed. The gradient section of the column was heated electrically with a spiral winding of nichrome wire. The spiral pitch decreased from 2 cm at the lower end of the column to 0.5 cm near the top. The temperature gradient ranged over 4.0–1.5 °C cm⁻¹ in the zone of superheat nucleations. The lower section of the column was unheated to permit calculation of the droplet diameter from its rate of rise. Temperatures at which nucleation occurred (explosively) were measured with thermocouples immersed in the host liquid at the level of nucleation.

Solid particles were suspended in the pentane by stirring. The suspensions were unstable and were stirred immediately before use. Pentane/chloroform solutions were also used because the polar chloroform improved the stability of the suspensions of carbon black. We found that superheat limits of the particle-free pentane/chloroform solutions were in approximate agreement with the molar average superheat limits of the pure components¹¹, and that the effect of carbon particles on the superheat limit of the mixed solvent was generally less than on the pure solvent. The chloroform not only stabilised the carbon but inhibited its nucleation propensity.

Our primary results are summarised in Table 1 and Fig. 1; the latter shows histograms of the percentage of total nucleation events against temperature. The nucleation temperatures for alumina (Fig. 1*a*) and sericite suspensions (Fig. 1*b*) are narrowly distributed, with means at 144.1 °C and 145.4 °C, respectively. The superheats attained with carbon black suspensions are lower (139.4 °C) and more broadly distributed, probably because of adsorption of gas on the carbon particles. Figure 1*c* is a histogram for a carbon black/pentane suspension (run 6-12A) which was refluxed for 18 h to drive off entrapped gas before injection into the superheating column. The deviation of nucleation temperatures is narrower, and the mean temperature of nucleation higher than for carbon suspensions with shorter pretreatment times.

Table 1 Superheating of suspensions

		Particle	Run no.	Soak time	Soak temperature (°C)	Mean particle diameter (μm)	Bulk volume % solids in test droplet	No. of observations	Mean ebullition temperature (°C)	Standard deviation
50/50 vol. % pentane/chloroform		None	4-3F	—	—	—	—	34	156.4	3.07
		Carbon black (Sterling R)	4-6AG	1 h	24	0.075	0.6	28	155.1	2.69
		Carbon black (MT-X25)	4-3E	1 h	24	0.47	4.0	32	153.8	2.20
		Carbon black (MT-X25)	4-4DI	1 h	24	0.47	6.0	32	150.5	3.81
100 vol. % pentane		None	3-6A	—	—	—	—	69	146.5	0.96
		Sericite	3-14AC	1 h	24	50.2	14.0	72	145.4	1.76
		Alumina	3-15A	1 h	24	0.06	12.0	108	144.1	1.57
		Carbon black (MT-X25)	3-15B	1 min	24	0.47	10.0	41	110.2	10.1
			3-11E	15 min	24			121	126.5	10.7
			3-11D	1 h	24			136	131.4	8.4
			3-11C	3 h	24			94	132.4	8.82
			2-28	1 h	31.6			143	133.0	4.50
			6-12A	18 h	31.6			80	139.4	6.53

Fig. 2 Electron micrograph of sericite particle. Scale bar = 40 μm .

Carbon black particles are hydrophobic, whereas the alumina and sericite are hydrophilic. The consequent different wettabilities do not explain the observed superheat limit differences, that is, that the hydrophilic particles show a higher limit than the hydrophobic.

In general, the results are consistent with the nucleation theory of Volmer⁶, as extended by Cole¹², Jarvis¹³ and Eberhart¹⁴. The theoretical effect of interfacial energies on the limit of superheat would be that a change in wetting angle from 0° to >90° changes the calculated limits of superheat by only 2–3 °C. The difference in the superheat limits observed for the carbon suspensions and the inorganic suspensions must therefore reside in the gas adsorption capacity of the former.

In spite of the agreement with nucleation theory, the results may seem counter-intuitive because we tend to think of a particle as a discontinuity in the liquid phase and, hence, a point where phase separation is likely to occur. The careful filtration and cleaning of fluids by other investigators would seem to have had little effect on their experimental results other than removing particles that contained entrapped gas.

Previous studies of superheated liquids in contact with solid surfaces other than freshly drawn glass or silica capillaries^{15–18} failed to produce superheats of pentane in excess of 10 °C, whereas this study produced superheats of 74–110 °C. That our surfaces are not smooth is evident from the electron micrograph shown in Fig. 2. Nevertheless, our liquid–solid interfaces suffer the initiation of a vapour phase about as reluctantly as does homogeneous liquid.

We thank Professor Lloyd Trefethen for bringing ref. 8 to our attention. This work was supported by NSF grant ENG-74-19478.

The problem of the thrown string

ULAM¹ reports that "there was another problem which Fermi wanted to study but which we somehow never came to formulate well or to work on. He said one day, 'it would be interesting to do something purely kinematical. Imagine a chain consisting of very many links, rigid, but free to rotate around each other. It would be curious to see what shapes the chain would assume when it was thrown on a table, by studying purely the effects of the initial energy and constraints, no forces'." Sygne² posed the problem of estimating the average $\bar{D}$ of the rectilinear distance D between the ends of a flexible string of length L when thrown down at random on a table. Later³ he published conceptual models and some experiments which together increased the challenge (recently restated by Kingman⁴): the models yielded values of $\bar{D}/L$ equal either to 0 or 1 unity, whereas in three experimental series by different throwers of different strings, the values obtained were 0.32 (100 throws), 0.34 (50 throws) and 0.38 (60 throws). (Only for the last of these was the value of $\bar{D}^2/L^2$ also recorded, at 0.18.) Sygne wrote³: "the agreement of the results is rather striking and one might hope to explain the numerical value (say 1/3) on theoretical grounds . . . I hoped that someone would suggest a way of treating directly a system with an infinite number of degrees of freedom, but perhaps no such way exists". Here we propose a solution along the desired lines by kinematical means.

Consider first the thrown string before it touches the table. Supposing that the rectilinear distance between its ends is x , how are the configurations of the string constrained by its continuity and its length? No element of the string can lie outside the ellipsoid having semi-axes $\frac{1}{2}L$, $\frac{1}{2}(L^2 - x^2)^{1/2}$, $\frac{1}{2}(L^2 - x^2)^{1/2}$, with the ends of the string at its foci; and any point within the ellipsoid may be intersected by the string. Thus the continuous nature of the string associates the accessible volume $\pi L(L^2 - x^2)/6$ with each value of x . We make this feature of the problem central to our treatment, and postulate that the probability density of x is proportional to the associated accessible volume. According to this postulate, if a large number N of throws is made, the number of cases for which the separation distance lies in the interval $(x, x + dx)$ is $3N(L^2 - x^2)dx/2L^3$, the proportionality factor being fixed by normalisation.

Next we introduce the vector $\mathbf{x}$ (of length x) from the lower to the higher end of the string, at the moment of impact of the string with the table, and model the effect on the separation distance of the collapse of the string onto the (horizontal) table, by projecting $\mathbf{x}$ on to the plane. Let θ be the smaller angle between $\mathbf{x}$ and the vertical. Assuming that the throws do not generate preferred values of θ , we adopt an isotropic distribution of (upwards) $\mathbf{x}$ -directions, and seek the distribution of projected lengths $D = x \sin \theta$. Consider the hemispherical surface of radius x lying flat on the table: its element belonging to the interval $(\theta, \theta + d\theta)$ contains the fraction $2\pi(x \sin \theta)(x d\theta)/2\pi x^2 (= \sin \theta d\theta)$ of the vertices of the vectors $\mathbf{x}$ drawn from the centre.

Then the number out of N throws for which, at impact with the table, the separation distance lies in $(x, x + dx)$ and the orientation angle in $(\theta, \theta + d\theta)$, is given by

$$n(x, \theta) dx d\theta = \frac{3N(L^2 - x^2)}{2L^3} \sin \theta d\theta dx \quad (1)$$

To obtain the observed distribution of the projections $D = x \sin \theta$, we change the independent variables x, θ in equation (1)

to x , D (Jacobian $(x^2 - D^2)^{-1/2}$), and integrate over x :

$$n(D) dD = \frac{3ND}{2L^3} \left[\int_D^L (L^2/x - x)(x^2 - D^2)^{-1/2} dx \right] dD \quad (2)$$

$$= \left[\frac{3N}{2L} \arccos(D/L) - \frac{3ND}{2L^3} (L^2 - D^2)^{1/2} \right] dD$$

Hence the probability density $\omega(\lambda)$ for the ratio $\lambda = D/L$ is

$$\omega(\lambda) = \frac{3}{2} [\arccos \lambda - \lambda(1 - \lambda^2)^{1/2}] \quad (3)$$

and for the density $\nu(u)$ of $u = D^2/L^2$ we find

$$\nu(u) = \frac{\omega(u^{1/2})}{2u^{1/2}}$$

Both ω and ν are convex and monotonically decreasing in the interval $(0, 1)$. While ω falls with only slight curvature from $3\pi/4$ to zero, ν falls from infinity to zero.

From equation (3) we obtain by straightforward integration the numerical values of the observables: $\bar{\lambda} = \bar{D}/L = 3\pi/32 \approx 0.29$, $\lambda^2 = D^2/L^2 = 2/15 \approx 0.13$. Considering the simplicity of our probabilistic postulate, these values compare favourably with the observations quoted above. At the conventional 0.05 significance level, there is no significant difference between the theoretical variance 0.046 and the observed variance 0.036, nor between the theoretical mean and the observed means in two of the experimental series. However, the differences of the theoretical mean from the largest observed mean, and from the mean of the pooled observations, are significant.

If the string was thrown so as to keep it in a plane parallel to the table throughout, the counterpart of ω would be constructed by replacing the ellipsoid by an ellipse, with the results $\bar{D}/L = 4/3\pi \approx 0.42$, $D^2/L^2 = 0.25$. We note that all the observed means lie between those calculated from the ellipsoid and from the ellipse, and the observed mean square is correspondingly bracketed. This may be because (some of) the throws were made near the table and along it.

How does the above analysis apply in the case of a segment of length L belonging to a longer string? In this case our original postulate might require non-trivial modification to take account of the presence of extraneous bodies, namely the extra portions of string. The problem of the thrown string has points of contact with properties of coiling macromolecules in solution, especially when approached as a limit of a chain^{3,5}. However, systematic results for the former problem depend on persisting effects of the randomisation of initial conditions, whereas for the coiling molecules results depend on the more special state of thermodynamic equilibrium, independent of initial conditions.

We thank Professor J. F. C. Kingman and G. B. Price for interesting discussions.

The crystal structure of a hydrated gramicidin S-urea complex

THE cyclic decapeptide antibiotic gramicidin S has the sequence

Since its isolation by Gause and Brazhnikova¹, several authors have proposed possible conformations²⁻¹⁰. Of these models, the one that has gained most general acceptance is that of Hodgkin and Oughton², who proposed that the structure consisted of two β -chains linked by proline residues and stabilised by four intramolecular hydrogen bonds. Several derivatives of gramicidin S have been crystallised^{8,11}, but it had not been possible to solve any of the structures¹². We now report the structure of a gramicidin S-urea complex in which the gramicidin molecule has a conformation somewhat distorted from the Hodgkin-Oughton model.

In the presence of urea and HCl, gramicidin S crystallises as yellow elongated prisms from a solution in 95% ethanol. Crystal data: trigonal, $a = 25.8$, $c = 21.49$ Å, space group $P3_121$, $D_m = 1.10$, $D_c = 1.06$ (based on $C_{60}N_{12}O_{10}H_{92} \cdot \frac{1}{2}[(NH_2)_2CO] \cdot 8H_2O$, $Z = 6$). Data collected on a Hilger and Watts Y290 4-circle diffractometer consisted of 5,695 observed reflections out of 6,353 measured. Because of crystal instability it was necessary to use several crystals during data collection.

Fig. 1 Most of the side chains are omitted from the diagrams for the sake of clarity. *a*, A view of the molecule showing the four inter-chain hydrogen bonds, and the essential similarity of the structure to that proposed by Hodgkin and Oughton. *b*, A view showing the twist in the molecular backbone, and the unpredicted hydrogen bond involving the ornithine side chain. *c*, *d*, Two views related to each other by a rotation of approximately 180° , showing that the molecular backbone has approximate 2-fold symmetry.

The structure was solved by use of the multiple-solution direct methods program MULTAN¹³ developed in this laboratory. 100 phase sets were generated for 350 reflections ($E_{\min} = 1.86$), using 4,897 triple-phase invariants. The starting set consisted of one origin-defining and six other reflections (one with restricted phase and five with general phases). The phase set with the greatest combined figure of merit corresponded to an E -map which contained a 58-atom molecular fragment, and subsequent weighted E -maps revealed the remainder of the molecule and one half-molecule of urea.

The atomic coordinates and isotropic temperature factors were refined by the diagonal least-squares method, using fast Fourier transform techniques to generate structure factors and

gradients¹⁴. Refinement based on the 4,902 observed reflections within the sphere of 1.0 Å resolution gave an *R*-factor of 0.188, with approximate estimated standard deviations for the positions of carbon atoms within the main chain of 0.04 Å. The isotropic temperature factors (*B*) ranged from 5.0 to 25.1 Å². Because of the high thermal motion and the limited quality of the data, there is some uncertainty in the positions but not the presence of some of the side-chain atoms.

The molecular structure is basically similar to that of the model proposed by Hodgkin and Oughton². Figure 1a shows the four hydrogen bonds predicted from the model. The molecular backbone, however, is twisted from that of the model in such a way as to retain the approximate 2-fold symmetry but so that the hydrogen bonds between the two halves of the molecule are no longer parallel (Fig. 1b–d). In addition to these four intermolecular hydrogen bonds, there is an intramolecular hydrogen bond (N–O distance –2.88 Å) between one of the ornithine side-chain nitrogen atoms and the D-phenylalanine carbonyl oxygen atom which had not been predicted. The other ornithine nitrogen atom cannot take part in such a hydrogen bond but has a close, potentially hydrogen-bonded, contact to a water molecule.

The crystal packing is apparently stabilised by many hydrogen-bonding interactions. For each gramicidin molecule there is one half-molecule of urea (occupying a site on a crystallographic 2-fold axis) and eight molecules of water (six in general positions, two on 2-fold axes and one disordered between two sites approximately 1 Å apart). All these small molecules are within hydrogen-bonding distance, either of the gramicidin molecule or of each other. In addition to the possible intermolecular hydrogen bonding involving the small molecules, there is a hydrogen bond between atoms in the backbone of two gramicidin molecules related by a 2-fold axis (N–O distance –2.73 Å). All the polar atoms in the gramicidin molecule are involved in short, probably hydrogen-bonding, contacts of one of the types mentioned above, as are all the solvent molecules.

We are continuing our efforts to obtain more accurate data for the structure.

We thank the SRC for its support of this investigation; R.K. thanks the British Council for the award of a Research Fellowship.

Thermoluminescence dating of sediment baked by lava flows of the Chaîne des Puys

AN earlier attempt¹ to use thermoluminescence (TL) for determining the age of Quaternary lava flows, and in particular of the magnetically reversed² Laschamp and Olby flows of the Chaîne des Puys in the French Massif Central, was frustrated by anomalous fading of the TL. This anomalous fading seems to be exhibited by most of the TL-sensitive minerals in lava and is probably due to wave mechanical leakage of electrons out of traps to nearby defects^{3,4}. It has not been observed in quartz¹ but only minimal quantities of this mineral are present in the basaltic flows of the Chaîne des Puys. Although the TL phototransfer technique is a promising⁵ way of using traps that are immune to anomalous fading, it has not yet proved possible to obtain TL dates directly from volcanic lava (although an empirical technique has achieved relative dating in one particular application⁶). We report here the TL dates for the baking by lava of clay and sediment, thereby avoiding the malign TL characteristics of the lava itself. TL dating of baked clay in the form of archaeological pottery is well established⁷ and the procedures developed in that application were followed here. Some of the dates obtained are of particular interest because of the likely association² of one of the lava flows concerned, that at Royat, with the magnetically reversed flows mentioned above. An average TL age for the latter of $33,000 \pm 4,000$ yr has been obtained by Valladas *et al.*^{8,9}; this is based on quartz extracted from a granitic inclusion found in the Laschamp flow and an underlying quartz pebble heated by the Olby flow.

Table 1 lists the results obtained from two exposures of baked sediment that had been heated by the Royat flow; this flow originated in the region of the Petit Puy de Dôme and moved down the valley of La Tirectaine through Fontanas and Royat to Chamalières (see ref. 10). The upper of these two exposures (samples *j1*, *j3.1*, *j3.2*, *j11* and *j42*—pointed out to M.J.A. by A. Roche in September 1976) lies in Royat on the North side of the Avenue de la Vallée facing the entrance to the car park (on the west side of which is La Grotte des Laveuses). The sediment at this location was plentiful and consisted of well consolidated red baked clay firmly adhering to lava at one boundary. Palaeomagnetic measurements by Barbetti and Flude (personal communication) on two orientated samples of the baked clay collected at the same time as those for TL gave directions within

Fig. 1 Plateau test; the ratio of natural TL to natural plus artificial TL as a function of glow-curve temperature, for *a*, reddened layer (*j1*); and *b*, unreddened layer (above *j1*). Other unreddened layers show similar behaviour. The artificial dose was 9 krad for *a* and 17 krad for *b*.

Table 1 Royat locations (45°45' N, 3°03' E)

Sample	Ancient dose (krad)	Water content (% of dry weight)	Dose-rates (rad yr ⁻¹)			TL age (yr × 10 ⁻³)
			Effective α	β	γ + cosmic	
Upper location						
j1	9.0	24	0.125	0.139	0.11	24 ± 2.7
j3.1	11.2	20	0.085	0.132	0.11	34 ± 3.6
j3.2	9.9	20	0.137	0.132	0.11	26 ± 2.7
j11	8.9	24	0.156	0.157	0.11	21 ± 1.8
j42	11.2	26	0.109	0.126	0.11	32 ± 3.2
Lower location						
j32	14.3	27	0.198	0.182	0.12	29 ± 2.8
j34	14.0	23	0.161	0.186	0.12	30 ± 2.6

Mean age (weighted) = 25.8 × 10³ yr; standard error = 1.7 × 10³ yr; predicted error = 2.2 × 10³ yr (random plus systematic).

3° of the rather abnormal result found^{11,12} for lava samples collected from the same location (declination 62° W, inclination +70°, α₉₅ = 3.5°; location 24 in ref. 12). Similar ancient directions for this flow both in respect of lava and in respect of associated baked sediment were found¹³ some 75 yr ago by Brunhes and David!

The lower location (samples j32 and j34) was on the east boundary of the car park itself, ~5 m below the upper location and 75 m nearer to the centre of Royat (see ref. 14). The sediment here is dark red and only ~1 cm thick; it is overlain by ~30 cm of ashy volcanic debris on top of which is the lava flow itself. The baked sediment here was poorly consolidated and although palaeomagnetic measurements by Barbetti and Flude (personal communication) showed some scatter, the sample mean directions were within 15° of the result previously obtained for the lava^{11,12} (declination 74° W and inclination +63°, α₉₅ = 3.5°; location CF 22 in ref. 12). A radiocarbon determination by Delibrias *et al.*¹⁵ for carbon extracted from the underlying soil at this locality gave an age of 11,070 ± 200 radiocarbon yr (Gif 2255) and on the basis that it is from a well protected palaeosol, this has been taken¹⁴ to be the maximum age for the lava. The palaeomagnetic results from the two locations indicate that they are stratigraphically equivalent.

The TL ages determined for these two locations, given in Table 1, were based on the fine-grain technique¹⁶; the error limits were evaluated as discussed elsewhere^{17,18}. The values for the combined γ + cosmic radiation dose-rates were obtained¹⁹ by burying small capsules of natural fluorite, for a year, in the sediment in a similar position with respect to the lava as had been occupied by the TL samples. Using our standard form of citation the average age derived from all seven samples is 25.8 × 10³ yr (±1.7 × 10³, ±2.2 × 10³, OxTL 132j). The two error limits quoted are^{17,18}, respectively, the standard error of the mean derived from the observed scatter of the individual ages, and the error predicted by taking into account random and systematic sources of uncertainty; the second limit is appropriate when comparing ages derived from other chronometric techniques.

There is a gross discordance between the TL age and the radiocarbon age mentioned above. This could arise in the radiocarbon determination if somewhat more than 20% of

the carbon in the sample was 'modern'. Although this is considered unlikely because of the well protected situation of the palaeosol and because of the pretreatment that was given to the sample to remove contaminating humic acid, this ¹⁴C age should be accepted with caution (G. Delibrias, personal communication, pointed out the desirability in these circumstances of evaluating the age of the humic acids). On the other hand, the TL age might be erroneously too old if there had been infiltration into the sample of unbaked sediment. This is inherently unlikely in the lower location because the overlying lava would have heated any material above the layer of burnt sediment, but error due to this factor is also considered to have been excluded by the following sample rejection procedure.

The presence of a significant amount of unheated material would be expected to cause a sample to fail the 'plateau test' that is routinely applied⁷ (see Fig. 1); this test demands that there is a substantial temperature region (350–450 °C in the present work) of the glow curve within which the ratio of ancient TL to artificially induced TL does not vary (by more than 10% in the present work). Measurements made, for each location, on the ashy material lying above the baked sediment showed a change in this ratio by a factor of about two between 350 and 450 °C; hence the 10% plateau criterion implies rejection of samples in which contamination exceeded 10%. This level might be serious if the equivalent dose carried by the contaminating material was vastly in excess of that carried by the baked sediment. However, the highest equivalent doses evaluated for overlying material were 7 krad at a glow-curve temperature of 350 °C and 18 krad at 450 °C. This corresponds to the overlying material having been heated at the time of the volcanic activity, as might be expected; that the equivalent dose at 450 °C is higher than that for the baked sediment correlates with a higher radioactivity, as observed, and the lower equivalent dose at 350 °C is consonant with the effects of the anomalous fading which, as mentioned previously, prevents TL dating of volcanic material itself. Similar plateau measurements were made on unreddened soil beneath the dated layer at the lower location; these indicated an equivalent dose of 16 krad at 350 °C and 40 krad at 450 °C.

The increase with depth of the equivalent dose (when evaluated at a glow-curve temperature of 350 °C) raises the question of whether the sediment was heated to a sufficiently high

Table 2 St Saturnin (45°36' N, 3°06' E)

Sample	Ancient dose (krad)	Water content (% of dry weight)	Dose-rates (rad yr ⁻¹)			TL age (yr × 10 ⁻³)
			Effective α	β	γ + cosmic	
i12 (quartz inclusions)	3.4	12	0	0.200	0.135	10.1 ± 1.3
i15 (quartz inclusions)	3.0	19	0	0.200	0.135	8.9 ± 1.8
i17 (fine grains)	3.1	24	0.156	0.185	0.137	6.5 ± 0.7

Mean age (weighted) = 8.1 × 10³ yr; standard error = 1.1 × 10³ yr; predicted error = 0.8 × 10³ yr (random plus systematic).

temperature for earlier TL to have been erased. Partial erasure is ruled out by the satisfactory plateau observed for the reddened layers—for partial erasure the degree of erasure at different glow-curve temperatures would vary strongly. Negligible erasure would have been highly unlikely so close to molten lava and can certainly be ruled out for sample *j1* which was actually adhering to a vertical face of lava which terminated the extent of the baked clay.

Accepting that the heating by the lava was sufficient for complete erasure, there is also the possibility that because of anomalous fading the age of 26×10^3 yr may be erroneously too young. Tests on artificially irradiated portions of all the samples listed in Table 1 showed that for a storage period of 6 months any decay was less than experimental uncertainty (3%). However, this does not rule out a significant effect over thousands of years and an attempt was made to utilize the quartz inclusion technique—as there was no evidence that quartz suffers from this malign phenomenon. Unfortunately, the yield of quartz was too small to allow the necessary comprehensive measurements for a reliable date but for sample *j1* the equivalent dose was estimated as 6–9 krad; this corresponds to an age of between 26×10^3 and 35×10^3 yr. Thus although one cannot rule out a small amount of anomalous fading in the fine grains it does not seem to have had a gross effect.

In conclusion, bearing in mind the suggestion² that because of its abnormal magnetic direction, the Royat flow may be associated with the magnetically reversed Laschamp and Olby flows, the TL results for the Royat flow are mutually reinforcing with those obtained by Valladas *et al.*^{8,9} for Laschamp and Olby. Note that the radiocarbon age for the first phase of the geomagnetic polarity excursion²⁰ detected in aboriginal hearths at Lake Mungo, Australia, is $\sim 30 \times 10^3$ yr (5,730-yr half-life), and that the thermoluminescence age²¹ for these hearths is $(33.5 \pm 4.3) \times 10^3$ yr.

We have also carried out TL measurements on clay baked by the lava flow at St Saturnin. The radiocarbon age for this flow, being based on wood carbonised by the lava, is much more secure than the palaeosol determination for the Royat flow. Hence it is of particular interest to ask whether in this case the TL dating is consistent with the radiocarbon determinations. The TL samples, of black baked clay, were collected from above the pathway below the chateau, close to the spot where carbonised wood for ^{14}C dating was obtained by A. Rudel. Unfortunately, the TL characteristics were not all satisfactory and in view of this, the agreement (see Table 2) with the ^{14}C age of $7,650 \pm 350$ radiocarbon yr (Sa90) obtained by Pelletier *et al.*²² is better than could be expected; using the 5,730-yr half-life, the ^{14}C age becomes 7,880 yr and eventual availability of bristle cone pine calibration may show the corresponding calendar age to be greater still. The relevant γ dose-rates were obtained, as for the Royat locations, by burial of small capsules of natural fluorite. Table 2 shows that the standard error is comparable with the predicted error; this reflects the unsatisfactory TL characteristics mentioned above and indicates incidentally that in this application the system for evaluation of predicted error has been insufficiently pessimistic.

Finally, for some samples (provided by G. Camus), measurements were undertaken to check whether or not the flows concerned belonged to the period of Quaternary volcanism. As capsule measurement was not feasible for these samples the γ dose-rate had to be estimated from radioactive analysis of the material presumed to surround the sample. The fine-grain age evaluated for a sample of grès (from the quarry behind 120 Ave du Mont Dore, Beaumont) that had been heated by the Coulée de Boissejour was $\sim 50 \times 10^3$ yr and measurements made on quartz inclusions from this sample were consistent with this. Various other materials from this quarry were tried (baked clay, grès feldspathic) but none had sufficiently satisfactory TL characteristics for a reliable TL age to be determined. Clay from Montpoly that had been baked by the Coulée de Beaumont gave a fine-grain age of 34×10^3 yr. For calcaires trempés from the Butte de Clermont the plateau test⁷

indicated that there had been strong fading in the 330°C peak—indicating either that the material had not been heated in the eruption or that, on the basis of the equivalent dose indicated by the 420°C peak, it had been heated more than half a million years ago.

We thank Professor A. Roche and Dr G. Camus for help in locating the flows concerned, Dr G. Delibrias for discussion of the radiocarbon dating of the Royat palaeosol, and Dr M. F. Barbetti for his palaeomagnetic results

Changing He/Ar and N₂/Ar ratios of fault air may be earthquake precursors

THE geochemical method for the prediction of earthquakes depends on the ability to find the anomalous change of fluid phases of the ground, which are expelled by the stress at depth before earthquakes. Here the utility of ratios of He/Ar and N₂/Ar in fault airs is examined in this context

The radon emanation of groundwater may be a useful indication of the precursory effects of earthquakes¹. Helium may also be of interest, because unlike radon, helium does not decay but accumulates in the lithosphere. Use of only a single element for predicting earthquakes, however, is less reliable in some cases. A rare gas in the groundwater is lost through bubbling² and the concentration of the rare gas is lowered by other gases such as methane and carbon dioxide formed in the ground. Hence, it seems most appropriate to study the relative concentrations among gases and the ratios of He/Ar and N₂/Ar discussed here may prove to be the technically most useful parameters.

Helium and argon produced in the lithosphere are estimated from the abundances of radioactive elements (Table 1), and the ratio of helium to argon found to remain constant for the past several hundred million years irrespective of rock types. The ratio in the lithospheric air (~ 10) is 10^5 times higher than that in the atmospheric air (5.7×10^{-4}). The ratio in the atmospheric air becomes double the usual ratio because of the contamination of

Table 1 Abundances of U, Th and K in rocks and He/Ar ratios in the lithospheric air derived from the radioactive elements

	U	Th	K	He/Ar*	
	(p.p.m.)	(p.p.m.)	(%)	Myr	100 Myr
Basalt	0.83†	5†	0.58‡	10.8	10.8
Granite	3.96†	13.5†	2.50§	8.82	8.82
Shale	3.7	12	2.24¶	8.95	8.95

* The year represents the accumulation interval. The decay constants used for the calculation are as follows: $\lambda_U = 1.537 \times 10^{-10} \text{ yr}^{-1}$, $\lambda_{Th} = 4.99 \times 10^{-11} \text{ yr}^{-1}$, $\lambda_K = \lambda_{EC} + \lambda_{\beta} = 5.29 \times 10^{-10} \text{ yr}^{-1}$, $\lambda_{EC} = 5.7 \times 10^{-11} \text{ yr}^{-1}$. The abundance of ^{40}K in potassium is assumed to be 0.0119%.

† General average⁹.

0.005 vol % of the lithospheric air. Table 2 shows some examples of natural gas composition in Japan and USA. The concentrations of helium and argon are often lower than those in the atmospheric air, whereas the He/Ar ratios are much higher. This indicates that the lithospheric air permeates through the natural gases. The lithospheric air released by the formation of cracks in rocks, therefore, can be easily detected using this ratio.

The ratio N_2/Ar is also expected to be a useful parameter of lithospheric air, because the ratio in natural gases and volcanic gases is generally higher than that of the atmospheric air (85.21) (refs 3–6). The origin of nitrogen in the lithospheric air has been explained in terms of (1) the release of nitrogen by the bacterial decomposition of nitrogen-bearing compounds, (2) the release of nitrogen by the inorganic chemical breakdown of organic materials, and (3) the release of inorganic nitrogen from igneous (and metamorphic) rocks^{4,5}.

The ratios He/Ar and N_2/Ar are measured by gas chromatography without vacuum processes, temperature and pressure corrections and other complicated treatments. This technique is simple enough for amateur observers to make the appropriate measurements.

Since 1976 I have continuously measured the variations of He/Ar and N_2/Ar ratios of gas bubbles found in the water issuing from a fault zone almost 2 m wide which runs in chert and shale of the Palaeozoic. The fault crosses the precinct of Inuyama Crustal Movement Observatory of Nagoya University which is ~20 km north of Nagoya.

The gas bubbles are constantly gathered in a bottle set upside down in the water, then transferred into a glass flask with high vacuum stopcocks. Some of the gas sample (2 ml) is injected into the gas chromatograph, tank oxygen is used as a carrier gas. Helium, argon and nitrogen are separated through a molecular sieve 5 Å column at a room temperature, and the three peaks of these gases emerge on a recorder chart within 10 min. The relative areas of peaks correspond to the relative volumes of

gases in the sample and the mutual ratios among these gases are determined by the atmospheric air as a reference standard in the same conditions. Error (2σ) in the determination is ~10% for He/Ar ratios and ~2% for N_2/Ar ratios. If the gases were each measured by a different method, the error would inevitably be increased. The single procedure provides sufficient precision for analysing the ratios.

The successive measurement indicated that a high He/Ar ratio (0.014) was accompanied by the earthquake of 26 July 1976 (magnitude: 4.1; epicentral distance: 67 km), but the sampling interval (once or twice a month) was too long to decide whether the high ratio occurred before or after the shock⁷. The sampling interval was therefore shortened after March 1977 (once in two or three days).

Some correlation between occurring of earthquake and change of gas quality was observed, but the variation of the observed ratios has no relationship to the records of tiltmeter, extensometer and precipitation obtained in the observatory. The ratios of He/Ar and N_2/Ar fluctuated considerably: for the next 10 measurements, the moving average for data smoothing was calculated after March 1977. The results are plotted in Fig. 1, which shows that a few peaks appeared. The four vertical

Fig. 1 The temporal variations of He/Ar and N_2/Ar ratios in gas bubbles from the fault zone. The original data sequence was smoothed by 10-term moving averages after the usual process in statistics¹⁴. The vertical arrow indicates the earthquakes with the magnitude ≥ 4 in the vicinity of Nagoya. *M* represents magnitude and *D*, epicentral distance. See also Table 3.

arrows show the earthquakes (magnitude ≥ 4) which occurred in the vicinity of Nagoya during the observation. The three events of the four were felt in Nagoya (Table 3). Figure 1 shows explicitly that the peaks appear before the earthquakes. This correlation found can hardly be chance and suggests that the change of gas composition is closely related to the occurrence of an earthquake. The epicentral distance of the earthquake on 14 January 1978 amounts to 216 km, which greatly exceeds the size

of the dilatant volume generally accepted. According to the observation in China⁸, however, anomalous radon contents of groundwater were recorded at distances less than 110 km from the shock, for events in the magnitude range 4.3–5.0; for the larger quake of magnitude 7.9 in the Pohai Gulf, the wells showing radon anomalies were located at distances of 250–300 km. These observations suggest that the changes in gas composition reflect sensitively stresses which precede earthquakes and such changes could be precursors of earthquakes.

Several aspects arise from Fig. 1, in terms of earthquake prediction. The duration of the high ratio is longer for one large earthquake (14 January 1978, magnitude 7.0) than those for the small ones (magnitude ≈ 4). Another aspect is that the peaks of He/Ar precede those of N₂/Ar for all events. This might be attributed to the difference in diffusion velocity of He and N₂ through capillary cracks formed by stress before earthquake. The molecular weight of N₂ is 28 and of He is 4; the ratio of diffusion velocities is $\sqrt{28/4} = 2.65$ and He migrates more rapidly by diffusion than does N₂. It is also noticeable that the time lag of the N₂/Ar peak for the large earthquake is longer than for the others. Thus, by estimating both the time lag of N₂/Ar peak and the duration of high ratios, one could predict the occurrence time and magnitude of the approaching earthquake. Furthermore, observation in many locations may provide a basis for predicting where the earthquake will occur.

The earthquake of 14 January 1978 caused a disaster in the Izu Peninsula. Many observatories and seismology and geodesy instruments such as tiltmeter, extensometer and seismograph have been installed around the peninsula. These instruments did not record the premonitory phenomena for the earthquake except for a radon meter and a Sacks–Evertson strain meter. On the other hand, the method described here clearly records the precursory changes in gas compositions at the epicentral distance of 216 km. It seems therefore that this method is a promising practical means of predicting earthquakes.

I thank Drs R. Shichi and Y. Fakuo for assistance and helpful suggestions.

Seawater/basalt ratio effects on the chemistry and mineralogy of spilites from the ocean floor

PILLOW basalts metamorphosed to the greenschist facies have been frequently dredged from mid-ocean ridges^{1–3}. These rocks usually exhibit a distinct mineralogical differentiation in which the pillow rim or margin is replaced by chlorite or, less commonly, epidote. Calcic plagioclase and olivine within the pillow interior or core are replaced to varying degrees by albite and chlorite, respectively². Actinolitic amphibole, pyrite, quartz, sphene, and small amounts of nontronite and saponite are the other alteration phases identified in these rocks^{1–3}. Corresponding to this mineralogical differentiation is a chemical differentiation characterised, in general, by enrichment of MgO and H₂O in the pillow rim relative to the core; the core is in turn enriched in Na₂O, CaO and SiO₂. Cann⁴, in his study of the metamorphosed pillow basalts dredged from the Carlsberg Ridge, Indian Ocean, refers to the Mg-enriched, Ca-depleted, chloritised rind of the pillows as hyalospilites, and the Na-enriched cores as orthospilites. Metabasalts similar in chemistry and mineralogy to those dredged from mid-ocean ridges have also been found in ophiolites, obducted portions of oceanic crust now exposed on continents^{4,5}. The oxygen- and strontium-isotopic composition of these basalts^{6,7}, and the oxygen-isotopic composition of secondary minerals separated from dredged basalts⁸, suggest that alteration resulted from interaction with seawater at temperatures from about 200 to 350 °C. Passage of seawater through a sequence of pillow basalts would most probably occur along fractures and cracks between individual pillow tubes. In this regard, Spooner *et al.*^{6,7} from studies of the extent of hydration, oxidation and oxygen- and strontium-isotopic composition of metamorphosed pillow basalts at Troodos, Cyprus, have concluded that the flow of seawater through basalt pillow piles occurred primarily along fractures and pillow boundaries, whereas grain-boundary diffusion was the principal mechanism of mass transfer accompanying chemical reaction within the solid rock. Because of this variation in permeability, pillow rims would be exposed to a much greater volume of seawater relative to the crystalline cores; consequently, alteration of the rim would proceed at a higher effective water/rock ratio⁹. We propose here that the water/rock mass ratio during seawater–basalt interaction affects the stability of secondary minerals and therefore accounts for

Table 1 Chemical composition of basalt glasses

the mineralogical and chemical diversity between the core and rim of metamorphosed pillow basalts. To demonstrate this, we report the change in mineralogy and chemistry of basalt glass reacted with seawater at 300 and 350 °C, 500 bar at water/rock mass ratios of 62 and 10, respectively. The experimental system and analytical procedures are discussed in refs 10, 11.

Interaction of seawater with basalt glass at 350 °C, 500 bar, and water/rock mass ratio of 10 results in the formation of a mineral assemblage containing albite, saponite, mixed-layered chlorite-saponite, actinolitic amphibole and anhydrite, as well as minor prehnite, quartz and pyrite. In general, this alteration assemblage is similar to that in the cores of metamorphosed basalts. Furthermore, because of chemical exchange with seawater during this experiment, the basalt glass gained Na₂O, MgO and H₂O and lost CaO, SiO₂ and K₂O, while total iron and Al₂O₃ were conserved (Table 1). These directions of chemical

exchange, and for some species even the magnitude, are strikingly similar to those inferred during the transformation of tholeiitic basalt to orthospilite (compare columns 1 and 2 of Table 2). The one exception is SiO₂, which is enriched in the orthospilite samples described by Cann². During experimental 'spilitisation', SiO₂ is lost from basalt because fresh seawater contains very little SiO₂ and the tendency is for the solution to become saturated with quartz. Whether a rock in the natural setting becomes enriched or depleted in SiO₂ depends in general on whether the solutions which pass through it are supersaturated, as in the case of a cooling solution, or undersaturated with quartz. The enrichment observed by Cann may thus not be typical for orthospilites as a whole.

Further evaluation of the data (Table 2) reveals that, although Na is enriched in basalt during this experiment, the degree of enrichment is minor compared with that of the typical orthospilite. The formation of albite from basalt glass or calcic plagioclase depends critically on the Na/Ca ratio of the aqueous phase. If this ratio is large and remains large during seawater-basalt interaction, the basalt would generate potentially greater amounts of a sodic phase such as albite at the expense of calcic phases such as epidote or prehnite. Although seawater has an initially high Na/Ca ratio, reaction with basalt within a closed system results in a significant decrease in this ratio and in the tendency to form albite. For example, in the present experiment the Na/Ca molal ratio of the solution decreased from 45 to 13, partly by loss of Na but mainly by gain of Ca (M.J.M. and W.E.S., unpublished data). In nature, however, this build-up of Ca in the intergranular 'pore' solution within the crystalline core would be free to diffuse into zones having a lower Ca concentration and a higher Na/Ca ratio, such as the relatively less altered, more freely circulating seawater infiltrating interpillow channels (Fig. 1). Concomitantly, Na in this fluid could then

diffuse into the core and become fixed as albite; this process would account for the Na-rich chemistry of orthospilites. It is important to note, however, that if circulation of seawater within the interpillow channels is impeded for some reason, a decrease in Na/Ca ratio can be expected. This would alter the diffusion gradients of Ca and Na and ultimately result in the formation of calcic silicates as vein fillings. Phenomena of this sort may help to explain the 'epidote-rich' greenstones reported by Humphris and Thompson³, in which epidote typically occurs in veins.

Seawater-basalt interaction at 300 °C, 500 bar, and a water/rock ratio of 62 represents a seawater-dominated system¹², in which most of the CaO, Na₂O and K₂O as well as some of the SiO₂ are leached from the basalt (Table 1). At the same time, MgO and H₂O are added to the altered basalt, which was converted entirely to a mixed layered chlorite-smectite. The only other phases which formed were anhydrite and very minor haematite.

The exchange of components between seawater and basalt during alteration at a high water/rock ratio agrees well with the chemical gains and losses inferred from the chemistry of the chloritised rind (hyalospilite) of pillow basalts dredged from the Carlsberg Ridge (Table 2). Furthermore, interaction at a high water/rock ratio produces a solution appreciably enriched in Fe, Mn, Cu, Zn and SiO₂. The precipitation of these components, either in channels within the pillow pile or on the seafloor could explain the widespread jasper and ferromanganous sediment commonly associated with spilitised basalt.

The mineralogical and chemical heterogeneity commonly observed in metamorphosed seafloor basalts can, therefore, be explained on the basis of interaction with seawater at various water/rock ratios. Experimental seawater-basalt interaction at

Fig. 1 Schematic illustration depicting circulation of seawater through pillow basalt pile undergoing hydrothermal alteration: a, primary zone of Mg-metasomatism (high water/rock ratio); b, zone of alteration characterised by diffusional metasomatism (low water/rock ratio).

a low effective water/rock ratio produces an alteration assemblage characterised by albite, actinolite, prehnite, chlorite-smectite, quartz, pyrite and anhydrite. At a high water/rock ratio (62), in contrast, the basalt is strongly leached and replaced by chlorite-smectite. These results apply directly to the natural system, in which, because of the inherent permeability of pillow basalt piles, the pillow core has limited direct access to seawater and alters at a low water/rock ratio, whereas the glassy selvage of the pillow exterior apparently comes into contact with much greater volumes of seawater and consequently alters at a high water/rock ratio.

We thank Robert G. Coleman and Dave Piper of the US Geological Survey for critically reviewing the manuscript. This research was performed in the Stanford University Hydro-

thermal Laboratory, and at the US Geological Survey, Menlo Park, California. Funding was provided by NSF grant ID 074-12880.

Adaptive value, entropy and survivorship curves

NATURAL survivorship curves fall into three main types^{1,2}. Type I, or rectangular distribution, describes the situation in which all individuals attain the maximum physiological longevity of the species. Here the maximum age at death and the mean life expectancy coincide. The Type II life table describes a mortality which is independent of age; that is, no single age group is favoured at the time of dying. The Type III table is characterised by a high mortality early in life and a life expectancy which increases with the age of survivors. The three types of curve are illustrated in Fig. 1. The general shape of the survivorship curve is fixed for each species, however, the convexity of the curve is highly sensitive to environmental conditions and the genetic constitution of the population. This fact suggests that the general shape of the life table may provide information about the genetic variability in the population, the range of environmental factors that impinge on the population or the incidence of random events in the lifetimes of different individuals³. This note characterises in terms of two new demographic parameters the relative effect genetic and environmental factors play in the evolution of the life table. The analysis we give revolves around two demographic variables, the entropy of a population and the adaptive value. Entropy H measures the variability of the mortality distribution. The measure of variability also describes the convexity of the life table. The adaptive value ψ is a measure of the correlation between the variability of the mortality distribution and the environmental variability. Thus the adaptive value reduces to the entropy when the environment is constant.

We give two distinct characterisations of life-history curves in terms of optimisation arguments. In the first characterisation, we assume that the survivorship curves are completely determined by the genetic constitution. The life tables are derived by maximising H subject to constraints which are given a genetic interpretation. In the second description, we assume that the environmental effects are the only significant influence. The three life tables are derived in terms of maximising ψ subject to constraints on the environmental parameters. We

Fig. 1 The theoretically possible distinct types of life table. For Type I, $H = \log e^0$; for Type II, $H = 1 + \log e^0$ and $l(x) = \exp -(x/e^0)$; for Type III, $H = \frac{1}{2} + \log e^0$ and $l(x) = \exp -(\pi/4e^{0.2})x^2$.

also discuss the corresponding biological mechanisms which generate the life tables. Note that the genetic and environmental constraints which are imposed in the optimisation arguments correspond to initial conditions in the mechanistic description. These biological mechanisms can be mathematically described in terms of a birth and death process. This mathematical model together with a precise description of the correspondence between constraints and initial conditions is discussed elsewhere⁴.

Let $l(x)$ be the probability that an individual born at age zero survives to age x , and let $m(x)$ be the age-specific fecundity. The net reproductive rate R_0 is given by

$$R_0 = \int_0^\infty l(x)m(x) dx$$

The expectation of life of an individual aged x is

$$e^0 = \int_0^\infty l(x) dx$$

The entropy of the population⁴ is given by

$$H = - \int_0^\infty q(x) \log q(x) dx$$

where $q(x) = l(x)m(x)/R_0$ is the probability density function of the age of reproducing individuals. The expression H is a measure of the variability of the contribution of the different age-classes to the stable age-distribution. It also measures the convexity of the net-maternity function $V(x) = l(x)m(x)$. Fixing the fecundity, say $m(x) = 1$, we obtain

$$H = - \int_0^\infty \frac{l(x)}{e^0} \log \frac{l(x)}{e^0} dx \\ = - \frac{\int_0^\infty l(x) \log l(x) dx}{\int_0^\infty l(x) dx} + \log e^0$$

Normalising, we obtain

$$H^* = \frac{\int_0^\infty l(x) \log l(x) dx}{\int_0^\infty l(x) dx}$$

The expressions H and H^* measure the convexity of the survivorship curve. For the Type I life table, $H^* = 0$ and $H = \log e^0$. For the Type II life table, $H^* = 1$, and $H = 1 + \log e^0$.

An interesting application of our entropy parameter to the study of male-female mortality patterns is given in ref. 5.

The notion of an adaptive value of a population⁶ generalises the entropy concept to incorporate the effects of environmental forces on the life-history distribution. We refer to ref. 6 for a precise mathematical definition. In this note we give an intuitive account. We consider the population as a stationary stochastic process whose phase space, the set of all life histories is subject to perturbations by an environmental process. There

are thus two stochastic processes at work, the process described by the population and the process described by the distorting effects of the environmental action. We can therefore identify two entropies, H , the entropy of the population in the case when no environmental forces interfere, and $\hat{H}$, the conditional entropy, that is, the entropy of the perturbed process given that the unperturbed mortality distribution is known. The adaptive value ψ is defined to be

$$\psi = H + \hat{H}.$$

This function measures the correlation between the variability of the mortality distribution and environmental variability. Thus, in a constant environment, ψ is precisely the entropy H of the population.

We now describe the various distributions that maximise H subject to various constraints. We suggest biological interpretations of these constraints by specifying mechanisms which implement these adaptive strategies.

(1) The distribution that maximises H subject to the constraint

$$\int_0^{\omega} l(x) dx = 1$$

where ω is the maximum life expectancy, yields the Type I life table.

The mechanisms implementing this strategy can be described in terms of a mortality which is the end result of senescence or wearing out of the individual, the senescent process going on at the same time and at the same rate in each individual.

(2) The distribution that maximises H subject to the constraint on the mean of the distribution $l(x)$ is given by

$$l(x) = \exp\left(\frac{-x}{e^0}\right)$$

This yields the Type II life table. This curve describes great interindividual variation in the age at death. The variation can arise exclusively from interindividual genetic variability. In the Type I curve, there is no genetic variability, hence the senescent process is the same in each individual. This implies that the life expectancy and the maximum longevity of the species coincide. For the Type II curve, there is genetic variability, hence senescence is less uniform. The degree of genetic variability of the population is measured by the constraint on the mean of the mortality distribution.

(3) The distribution that maximises H subject to a constraint on the variance is given by

$$l(x) = \exp\left[\frac{-\pi}{4e^{0.2}}\right] x^2$$

Of the three curves described, Type III represents the greatest individual variability in the time of dying. The constraint on the variance is a measure of the genetic variability in the population. The senescent process in this case is much less uniform than that which generates the Type II life table.

It is important to note that these distributions can also be derived as a result of maximising the adaptive value ψ , subject to environmental constraints. Thus an environmental agent that is lethal to individuals irrespective of their genetic constitution and that kills off all individuals at some prescribed age ω will yield a life table whose variability is maximally correlated with the environmental action, that is, a Type I curve.

An environmental agent that acts randomly on the individuals of different ages and is indifferent to the ages of the individuals will yield a Type II curve. Finally, an environmental agent that is age-specific and selectively removes younger individuals will yield a Type III table.

Egocentric orientation is influenced by trained voluntary cyclorotary eye movements

A CYCLOROTARY eye movement is a motor response of the eye made around the visual axis. Counter-rolling of the eye, for example, occurs during lateral head tilt^{1–5}; conjugate rotary nystagmus can be induced by a large rotating field^{6–9}; and disjunctive cyclotorsions can occur during ordinary convergence^{10,11}. Because none of these torsional eye movements can be produced as an isolated voluntary response, eye torsion has always been classified as an involuntary response, a reflex. Using a visual-feedback procedure, however, we have trained humans to make conjugate voluntary cyclotorsional eye movements up to 30 degrees in magnitude¹². We have also demonstrated that these large torsional movements are not visually induced and can be made in the absence of any visual stimulus. Accompanying the training and performance of these eye movements were a number of striking illusions related to one's own sense of body orientation. Because these newly trained eye movements are unprecedented, it is of interest to characterise accompanying illusions in detail, comparing them with other illusions of self rotation induced through vestibular¹³ and visual^{14,15} inputs. In this paper we compare the effects of trained cyclorotary eye movements with head and whole body tilts, showing a quantitatively similar change in egocentric orientation for each type of tilt. As such, our findings suggest the possibility of shared mechanisms affecting the stability of one's internal frame of reference, both for eye and body movements.

The exact method of training and testing of voluntary torsion using visual biofeedback has been detailed elsewhere¹². A subject was seated in a dark room with head movements fixed by a full mouth bite plate. A vertical $11 \times 0.25^\circ$ flash was presented monocularly to generate a vertical afterimage. This afterimage was then imaged in space next to a line of light of equal colour, brightness and size (real line stimulus). The subject was instructed to keep this afterimage line matched parallel to the real line only by cyclorotating the eyes. With practice, the subject gradually acquired the ability to rotate the eye(s) to match greater and greater inclinations of the real line. These cyclorotations were trained at the rate of about $0.8^\circ \text{ h}^{-1} \text{ d}^{-1}$ for 35 d (Fig. 1a). Using similar methods for 5–10 h of additional training, subjects were trained to make torsional slow pursuit (Fig. 1b) and torsional saccades (Fig. 1c). Individual frame analysis of 35-mm slides or 16-mm motion pictures filmed simultaneously were used to objectify the cyclorotary eye movements. Measurements from photographs used radial iris markings or limbal-scleral blood vessel junctions in relation to a visible and stable reference marker. Accuracy of measurements was ± 10 min.

During initial training, but not during final experimentation, subjects often felt that their heads and bodies were 'rolling laterally' and sometimes experienced associated visual illusions. Accompanying these changes in egocentric orientation were intermittent sensations of stomach nausea, headache and general body fatigue. The most dramatic of these illusions occurred as a distinct 'hallucinatory barrage' at least twice to each subject during initial training. Associated with eyelid tremor, the nearly vertical and parallel lines would appear to move independently, becoming almost horizontal and also appearing curved or wiggly. Accompanying these peculiar visual illusions were very powerful sensations of body flotation

Fig. 1 *a*, Training of voluntary torsion. Maximum torsional range measured psychophysically (small symbols) or photographically (large symbols) plotted against hours of training. *b*, Voluntary cycloverlational slow pursuit. Solid line represents a tracing moving at the correct velocity of 1.6° s^{-1} . Photographed at 24 frames s^{-1} . *c*, Time course of a voluntary torsional saccade. Photographed at 64 frames s^{-1} .

and/or rapid downward falling in the direction of the voluntary cyclotorsion. Although self-induced, these sensations show similarities to those experienced by pilots in conditions in which conflicting visual and orientational information can occur¹⁶. It should be noted that these gross and episodic disorientations occurred only during initial training.

In this report, we restrict our quantitative observations to a more constant and milder sensory illusion of body tilt, persisting even after a long period of training. To examine this shift in egocentric orientation and to make comparisons with other situations involving vestibular and neck proprioceptive input, we have devised a control and three test situations. Two subjects felt a rod pivoted about its centre so as to rotate in the frontal plane and adjusted it to the apparent vertical in the dark under each of the following conditions (Fig. 2, top): (1) the real line stimulus was viewed in otherwise dark surroundings at one of several angles of tilt (S); (2) voluntary eye torsion was used to match an otherwise vertical afterimage to specific tilts of the real line (E); (3) a head tilt was used to match the orientation of the real line to that of the afterimage (H); and (4) head and body were both tilted by means of a rotating chair in complete darkness (B).

All tilts and rotations were presented in 3° increments over a range of $\pm 9.0^\circ$. In condition H, the reflexive counter-torsion of the eye was less than 1° (average 0.6°) for even the largest 9° tilts; consequently, actual tilts of the head are slightly underestimated. Before each trial, the experimenter randomly displaced the rotatable rod to ensure that subjects could not memorise hand or rod positions.

The results are graphed in Fig. 2 (bottom). Condition S, as a control, demonstrated that the presence of the inclined real stimulus line had essentially no influence on the subjects' sense of vertical, changing it by only 3% of the real line's tilt. Such a line has also been shown to induce essentially no torsional movements of the eyes¹². Therefore, it can be concluded that the presence of the inclined real line in conditions E and H is of little consequence.

Voluntary torsion (condition E), however, caused marked shifts in the position of apparent vertical as did the two other

conditions (H and B). All adjustments were overestimated in the opposite direction to eye, head or body tilts and by an amount which was virtually identical in all three conditions (Fig. 2). It should also be noted that the results for conditions H and B confirm previous reports^{17,18}. Because the results are so similar in the three conditions, we averaged the data and plotted a single regression line for each subject, arriving at a slope of 0.23 for subject C.H. and 0.43 for subject R.B. If 1.0 is defined as a gain factor whereby a perfect vertical rod adjustment could be made, a gain factor for the subjects' sense of vertical or egocentric orientation can be determined by adding 1.0 to each slope. Thus, C.H. and R.B. overestimated their turning by an average factor of 1.23 and 1.43, respectively.

These experiments suggest that for each subject, there is a constant overcompensation signal determining egocentric orientation, regardless of whether the eye is voluntarily rotated (voluntary cyclotorsion), the otoliths and neck proprioceptors are stimulated (head tilt condition), or the otoliths are stimulated without significant neck proprioception stimulation (whole body tilt). In this case of voluntary torsion, as well as for other examples of the perceptual effects of eye torsion^{17,19}, the compensatory signal could arise either as an outflow, originating from a torsional command centre, or as an inflow, originating from eye muscle receptors. The results do not indicate the source of the compensatory signal.

What is surprising is that the motor act of voluntary torsion, which is independent of vestibular or visual stimulation, can, by itself, induce quantitatively identical sensations to actual head and body rotations. This similarity suggests that there might be a common pathway for each effect. Electrophysiological

Fig. 2 A laterally rotatable rod was adjusted to perceived vertical in the dark by subjects in different conditions of rotation over a range of $\pm 9^\circ$ (top). The visual stimulus for each condition is shown: R, real line; A, afterimage line. Both R and A are set to vertical when eyes are at rest and straight ahead. Rotation conditions are defined as follows: S, real line stimulus rotation only (control); E, voluntary eye torsion defined by an afterimage match to tilts of the real line; H, head tilt defined by an afterimage line match to tilts of the real line; B, body and head tilt in complete darkness. Graph shows the change in perceived vertical as a function of rotation. Rod settings for conditions E, H and B were in the opposite direction to any direction of physical rotation (abscissa) by a factor of about one-third (average slopes of 0.23 and 0.43 for subjects C.H. and R.B.). Control condition (S) showed essentially no effect (average slope = 0.03). $n = 40$ for each data point. Error bars on regression lines indicate average s.e. mean for the combined data of C.H. (bottom line) and R.B. (top line), based on 468 df. R.B.: $\bullet$, S; Δ , E; $\blacksquare$, H; $\circ$, B; C.H.: $\circ$, S; Δ , E; $\square$, H; $\circ$, B.

recordings from the vestibular nerve, for example, show that moving visual scenes produce signals that are similar to a motion stimulus to the semicircular canals²⁰⁻²³, a result which could be the physiological basis for the recent finding that egocentric orientation can be altered by rotating visual fields¹⁴. Perhaps a similar sharing of circuitry exists with respect to the newly trained response of voluntary eye torsion.

Possible role of excretory/secretory products in evasion of host defences by *Fasciola hepatica*

RATS develop a marked resistance to reinfection with *Fasciola hepatica* after a single immunising infection^{1,2}. This resistance is apparent within 2 weeks of initial infection^{3,4} but diminishes in long-standing infections⁴. Resistance does not depend on the presence of the initial infection at the time of challenge², and operates against intraperitoneally implanted metacercariae, juvenile or adult flukes³ as well as against orally administered metacercariae. Implantation (subcutaneous or intraperitoneal) with adult flukes does not stimulate marked resistance to challenge^{3,5}, and these implanted flukes may persist for many months in the cysts which form around them in the rat. Resistance may be transferred by cells⁶ or, provided that it is given at the time of challenge, by immune serum⁷; serum administered 6-8 d after infection is not effective⁷. However, the flukes of the immunising infection persist in the rat in an apparently normal healthy condition^{1,2} and clearly evade the mechanism which controls challenge infections. We report here experiments which show that *F. hepatica* produces substances which are toxic to its host's lymphocytes and that these substances may protect the parasite from its host's immune defences.

Liver fluke excretory/secretory products (ESP) were obtained by incubating adult flukes, collected from sheep or rats, in dry, stoppered plastic tubes for 1-2 h at 37 °C. During this time the flukes expelled the major part of their caecal contents. This was separated by centrifugation and stored at -20 °C until required for use. ESP were tested for toxicity to rat splenic lymphoid cells using the method of van Furth and van Zwet⁸ and

Table 1 Effect of ESP on immunoadhesion of peritoneal cells to *F. hepatica*

Replicate		% Flukes with adherent cells		
		Control	Immune control	ESP
1	1	0	91.7	11.1
	2	0	73.8	16.7
	3	14.3	61.5	4.3
	4	10	76.0	8.3
	5	0	76.2	14.3
Mean		4.9	75.8	10.9

0.1-ml volumes of juvenile *F. hepatica* (~2,000 per ml) and immune rat peritoneal cells (6×10^6 per ml) in tissue culture medium 199 were incubated with 0.1 ml fresh normal rat serum+0.1 ml medium 199 (control), 0.1 ml fresh immune rat serum+0.1 ml medium 199 (immune control) or with 0.1 ml fresh immune rat serum+0.1 ml ESP (ESP). The % of flukes with adherent cells was noted after 90 min incubation at 37 °C. Mean of control compared with mean of immune control, $P < 0.001$; mean of immune control compared with mean of ESP, $P < 0.001$.

the results are shown in Fig. 1. Viability of control cells remained at the fairly constant level of about 60% throughout the 2-h incubation period, whereas cells incubated in the presence of ESP showed a decrease in viability from 66% preincubation to 19% after 2 h.

The relevance of this finding to the evasion of host defences by *F. hepatica* was demonstrated using an *in vitro* immunocytoadhesion system. Juvenile *F. hepatica* were obtained by the *in vitro* excystation of metacercariae. When incubated *in vitro* with fresh serum and peritoneal cells from *F. hepatica*-resistant rats, these juvenile flukes become heavily coated with cells which include many eosinophils (Fig. 2). No cellular adhesion is seen if serum from uninfected rats is used.

The effect of including *F. hepatica* ESP in this *in vitro* system is seen in Table 1. Incubation in normal rat serum gave a mean of 4.9% flukes with cells attached, whereas incubation in immune serum gave 75.8% flukes with attached cells. Inclusion of *F. hepatica* ESP as well as immune serum reduced the numbers of flukes with adherent cells to 10.9%. This reduction was statistically highly significant (Student's *t*-test).

Fig. 1 Toxicity of ESP to lymphoid cells *in vitro*. 0.2-ml volumes of normal rat splenic lymphoid cells (15×10^6 per ml) in tissue culture medium 199 were incubated with 0.2 ml medium 199 (solid line) or 0.2 ml ESP (broken line). At 30-min intervals equal volumes of cell suspension and 0.2% Trypan blue were mixed and the % of viable cells determined.

Fig. 2. Immune adhesion of peritoneal cells to *F. hepatica*. 0.1-ml volumes of juvenile *F. hepatica* (~2,000 per ml) and immune rat peritoneal cells (6×10^6 per ml) in tissue culture medium 199 were incubated at 37°C for 15 min with 0.1 ml fresh immune rat serum. Wet preparation 400× magnification.

Cellular attachment is likely to be a first step in the immune killing of *F. hepatica* and the above results clearly show that *F. hepatica* ESP prevent this attachment in the *in vitro* situation. It seems highly probable that ESP also have a similar role *in vivo*, where they are maintained in intimate contact with the fluke in the bile duct or in the fluke's migratory tract in the liver.

It is thus proposed that the actively feeding liver fluke protects itself from host immune defences by producing substances which are toxic to its host's lymphocytes and other immunocompetent cells. This hypothesis is consistent with certain facts known about *F. hepatica* and its relationship with the rat. For example, very young flukes not producing effective quantities of ESP would be expected to be the immunogenic stage of infection, and older, actively feeding flukes would be nonimmunogenic. The early development of resistance after initial infection, the waning resistance in long-standing infections and the lack of resistance after implantation with adult flukes are thus explained. The importance of timing of passive serum transfer is also explained; transfer at the time of challenge, before flukes are producing ESP will be effective, but transfer later, when ESP are being produced in effective quantities, will not confer protection.

Further details of *in vitro* and *in vivo* immune adhesion of cells, particularly eosinophils, to *F. hepatica* will be published elsewhere, and electron microscopic studies of the immune killing of *F. hepatica in vitro* and *in vivo* are in progress.

Membrane noise and conductance increase during single spermatozoon-egg interactions

ALTHOUGH one of the earliest events of fertilisation of the sea urchin egg is a depolarisation and decrease in resistance of the egg plasma membrane¹⁻³, it is not known exactly what change occurs immediately after the interaction with a single spermatozoon. We report here that in *Paracentrotus lividus* this change is a depolarisation step of 1-2 mV, occurring 13 s before the main electrical change. The step is accompanied by an increase in cell noise and a decrease in resistance. In other biological membranes, such an observation has been interpreted as the introduction of ionic channels into the membrane^{4,5}. From this analogy we calculate that the single channels introduced into the egg plasma membrane during fertilisation have a conductance greater than 33 pS.

At sperm densities of 10^7 ml⁻¹ or greater we observed a fertilisation action potential similar to that already reported by Steinhardt *et al.*¹ (their Fig. 3) and Ito and Yoshioka³ (their Figs 2 and 3). In their recordings the depolarisation was composed of two phases. The initial phase has been called the shoulder of the action potential³. Closer observation of our records shows that the shoulder is composed of discrete events.

Progressively reducing the sperm density changed the configuration of the shoulder. For example, at a sperm density of 10^6 ml⁻¹, a shoulder was composed of three or four discrete steps, whereas at densities below 10^5 ml⁻¹ it was composed only of a single step. At very low densities, such as those used in Fig. 1a, it was not uncommon to wait several minutes for a reaction to occur. Both single steps and shoulders lasted for 13 s at 22°C.

The single step is the minimum detectable event during the shoulder phase of the fertilisation action potential. Eggs displaying the minimum event cleave normally. As sea urchins cleave abnormally if more than one sperm enters the egg, we deduce that a step corresponds to the successful interaction of the fertilising spermatozoon. Eggs which display shoulders cleave abnormally and are polyspermic.

Rothschild and Swann^{6,7} have shown for *Psammochinus miliaris* that at sperm densities of 10^5 ml⁻¹, the number of sperm-egg collisions will be 0.16 s⁻¹. The probability for a successful collision was measured as 0.12, so that on average, the successful encounter rate should be once every 50 s. This supports our interpretation that a step corresponds to one successful encounter.

A typical step and fertilisation action potential is shown in Fig. 1a. Steps were always accompanied by an increase in voltage noise. Lowering the temperature prolonged the step. At 22°C the average duration was 10.9 ± 1.8 s ($n = 12$), and at 12°C the average duration was 25.0 ± 4.3 s ($n = 3$). Similarly the rise time of the fertilisation action potential decreased from 1.13 ± 0.54 mV s⁻¹ to 0.27 ± 0.09 mV s⁻¹.

Figure 1b shows a step during an experiment carried out at 5°C in which the duration was 79 s. The longer step allowed a reasonable time for spectral analysis of the noise increase, and for an estimate of the change in variance before and after the step. This analysis is shown in Fig. 2. The voltage noise during the step increased primarily in the low frequencies. At rest, membrane resistance may range from 4 to 18 KΩ cm² (egg diameter 80 μm); during a step the resistance was always reduced by one-third to one-half.

To obtain an estimate of the elementary conductance change contributing to a step, we calculated the ratio of the change in noise variance to the change in potential. This ratio for Fig. 1b was 10 μV, which may be taken as the size of the elementary event contributing to the noise. Taking the specific resistance of

the egg during the step at its mean value of $6 \text{ K}\Omega \text{ cm}^2$ ($30 \text{ M}\Omega$), the current associated with this elementary event was 0.33 pA . To calculate the conductance through which this current passes, an estimate of the equilibrium potential of the step is required.

Progressively offsetting the resting potential towards zero, using a second intracellular electrode, resulted in a gradual decrease in the size of the step. At -3 mV , a step was difficult to observe and the noise increase was minimal; however the fertilisation reaction still occurred. This experiment suggested an equilibrium potential near zero. It was not possible to invert the step as fertilisation was suppressed when the egg was held positive, as reported elsewhere⁸.

Using the data from Fig. 1b, with a resting potential of 10 mV , the elementary conductance was calculated to be 33 pS . Repeating the calculation for three other examples gave the values 16 , 41 and 92 pS . In none of these cases was the resistance measured simultaneously with the noise. These values are large compared with the conductance of ion-specific channels, for example, Na and K channels in nerve membranes; however, they are similar to nonspecific drug-induced channels^{4,5}.

In the absence of Ca^{2+} a step did not occur; if calcium was added a normal step was observed and development ensued. The step seems to be a general phenomenon in sea urchins, as we have also seen it in *Psammechinus* and *Arbacia*.

What is the relationship between the electrical events constituting a step and the morphological events which occur during fertilisation? Possibilities include labile attachment of the spermatozoon to the vitelline membrane, strong attachment either to the vitelline membrane or egg plasma membrane, or fusion of the two gametes. Also, the acrosomal reaction is

Fig. 1 *a*, Intracellular recording from a mature egg of *Paracentrotus lividus* during fertilisation. Sperm density was 10^3 ml^{-1} . Egg jelly was removed by acid seawater ($\text{pH } 5.0$). The fertilisation action potential is the transient change in membrane potential shown in the latter half of the upper trace. The fertilisation potential is preceded by a step. The upper trace was d.c.-coupled whereas the lower trace, a.c. coupled from 1 Hz , demonstrates the noise increase during the step. (The noise trace saturates during the fast rise of the fertilisation action potential, and is omitted.) Vertical bar represents 12 mV (upper), 1 mV (lower); horizontal bar represents 5 s and also indicates the zero potential level. Temperature was 25°C . *b*, A step at 5°C . Vertical bar represents 6 mV (upper), 1 mV (lower); horizontal bar represents 5 s and indicates zero potential level.

Fig. 2 Power spectral density of voltage noise from the experiment shown in Fig. 1b. *a* microelectrode noise before the experiment; *b*, cell noise before the step; *c*, during the step; *d*, microelectrode noise after pulling out of the egg. About 40 s of data were used to estimate *b* and *c*; only half this amount for *a* and *d*. The microelectrode noise although increased after the experiment was well below the cell noise during the step. The spectra are limited by a.c. coupling at 1 Hz , and the time constant of the membrane.

generally considered as a prerequisite to sperm entry⁹. Aketa and Ohta¹⁰ have shown in *Pseudocentrotus* that the acrosomal reaction occurs following attachment to the vitelline membrane.

Arbacia spermatozoa made labile attachments to *Paracentrotus* eggs, but such attachments were not accompanied by an electrical change. However, at $\text{pH } 9.4$ a normal step and fertilisation action potential occurred qualitatively similar to that recorded for homologous fertilisation of either species. High pH alone did not activate the eggs; however, *Arbacia* sperm exposed to high pH underwent the acrosomal reaction as reported elsewhere¹¹. We deduce from this evidence that the step is subsequent to the acrosomal reaction. This interpretation would also explain the absence of the step in Ca^{2+} free seawater because the acrosomal reaction is Ca^{2+} dependent¹¹.

We suggest that a factor is released from the acrosomal vesicle which causes directly or indirectly the introduction of conductance channels into the egg plasma membrane. Introduction of many conductance channels into a membrane would result in a depolarisation and a noise increase and a decrease in resistance^{4,5}. Although our results do not rule out cell fusion as giving rise to the step, the conductance increase cannot be explained by the introduction of a simple hole into the egg plasma membrane.

Enzymatic methylation of phosphatidylethanolamine increases erythrocyte membrane fluidity

PHOSPHOLIPIDS are a major component of biomembranes and provide the fluid matrix for protein movement and organisation. Membrane fluidity has been closely related to the biological and biochemical processes such as transport of chemicals, cell fusion, and protein rotation and diffusion^{1,2}. Genetic, nutritional and temperature manipulation have been used to alter the fluidity of the cell membrane^{3,4}, but physiological and biochemical events that regulate membrane fluidity are still unknown. We report here that the enzymatic methylation of phosphatidylethanolamine in erythrocyte membranes induces a marked increase of the bulk membrane fluidity.

An examination of the role of phospholipid methylation in the regulation of membrane fluidity was prompted by the find that two methyltransferases are involved in the conversion of phosphatidylethanolamine to phosphatidylcholine⁵. These enzymes were found to be asymmetrically distributed in the erythrocyte membrane. The first enzyme that converts phosphatidylethanolamine to phosphatidyl-N-monomethylethanolamine faces the cytoplasmic side, whereas the second enzyme that adds two additional methyl groups from S-adenosyl-L-methionine to form phosphatidylcholine is located on the external surface of the erythrocyte membrane⁶. The substrate for the first methyltransferase, phosphatidylethanolamine, resides mainly on the cytoplasmic side and the product of the second methyltransferase, phosphatidylcholine, is present largely on the external surface of the membrane^{6,7}. Thus, translocation of phospholipids from the inside to the outside of the membrane is facilitated by a stepwise methylation of phospholipids. The enzymatic methylation of phosphatidylethanolamine to phosphatidylcholine takes place within the membrane, Mg²⁺ playing a critical part⁶. To examine the effect of such phospholipid rearrangement across the membrane on the lipid fluidity, the following experiments were carried out.

Fresh samples of blood were obtained from ether-anaesthetised male Sprague-Dawley rats (150 g) by cardiac puncture using heparin as anticoagulant. The erythrocytes, washed with 0.9% NaCl solution, were haemolysed with 40 volumes 5 mM Tris-phosphate buffer, pH 8.0, containing 1 mM MgCl₂ (ref. 8). The ghosts thus obtained were suspended into 10 volumes 50 mM Tris-glycylglycine buffer, pH 8.0, containing 5 mM MgCl₂. After centrifugation at 4 °C, 0.3 ml of packed ghosts were suspended in 0.7 ml of the same buffer, containing various

Fig. 1 Effects of incubating erythrocyte ghosts with S-adenosyl-L-methionine and S-adenosyl-L-homocysteine on membrane microviscosity. Erythrocyte cell ghosts were preincubated at 4 °C in 5 mM MgCl₂ and 50 mM Tris-glycylglycine buffer, pH 8.0, containing a 50 μM S-adenosyl-L-methionine (●); b, 50 μM S-adenosyl-L-methionine and 2 mM S-adenosyl-L-homocysteine (▲); c, control (□). The ghosts were then, resealed and labelled with DPH at 37 °C for 1 h. The amount of methyl group incorporated into lipids was 9 pmol per mg protein and 0.5 pmol/mg protein in the absence and presence of S-adenosyl-L-homocysteine, respectively. The calculation of the microviscosity at 25 °C was made according to the method of Hare *et al.*¹⁰.

concentrations of S-adenosyl-L-methionine and/or S-adenosyl-L-homocysteine, and incubated overnight (approximately 16 h) at 4 °C. Before use, the ghosts were washed with 10 volumes of a solution containing 150 mM NaCl, 10 mM Tris-HCl buffer, pH 8.0, and 5 mM MgCl₂ (solution A). The fluorescent probe, 1,6-diphenyl-1,3,5-hexatriene (DPH) was used for the measurement of microviscosity by the method of Shinitzky and Barenholz⁹. Fluorescence labelling was carried out by incubating the red blood cell ghosts in the solution A containing 1 μM DPH at 37 °C for 1 h. Labelled cells were washed and suspended in solution A at a concentration of 0.1-0.2 mg cell protein per ml.

The microviscosity of the erythrocyte membrane was found to be a function of temperature but no phase transition was apparent over a temperature range of 6 to 36 °C (Fig. 1). S-adenosyl-L-methionine was introduced inside the ghosts by preincubation at 4 °C. When the resealed ghosts were labelled with DPH at 37 °C for 1 h, the methylation of phospholipids as determined by procedures described previously⁵ took place simultaneously, but no significant methylation was observed at 4 °C. When S-adenosyl-L-methionine was present inside the ghosts, the microviscosity markedly decreased (Fig. 1). This reduction was almost completely abolished when S-adenosyl-L-homocysteine was present inside the cells together with S-adenosyl-L-methionine. S-adenosyl-L-homocysteine inhibited the methylation of phosphatidylethanolamine and itself did not affect the membrane microviscosity. These results indicate that

Table 1 Correlation between microviscosity changes and amount of phosphatidyl-N-monomethylethanolamine formed

SAM (μM)	[³ H]-methyl incorporation (pmol per mg protein)			Microviscosity (P)
	PME	PDE	PC	
0	—	—	—	1.62
4	1.15	<0.01	<0.01	1.32
12	1.80	0.1	0.1	1.18
25	1.90	0.50	0.40	1.08
50	1.95	1.20	1.50	1.06
100	1.97	2.40	3.60	1.09

SAM, S-adenosyl-L-methionine; PME, phosphatidyl-N-monomethylethanolamine; PDE, phosphatidyl-N,N-dimethylethanolamine; PC, phosphatidylcholine. Varying amounts of S-adenosyl-methyl-³H-L-methionine were introduced into rat erythrocyte ghosts and incubated as described in Fig. 1. The methylated phospholipids formed enzymatically were quantified after separation by thin layer chromatography with the solvent system, n-propyl alcohol/propionic acid/chloroform/water (3/2/2/1 v/v/v).

Fig. 2 Effects of various concentrations of S-adenosyl-L-methionine on microviscosity. Erythrocyte blood cell ghosts were preincubated at 4 °C with various concentrations of S-adenosyl-methyl-³H-L-methionine and then labelled with DPH at 37 °C to measure microviscosity. A part of the mixture equivalent to 0.2 mg protein was examined for ³H-methyl incorporation into the lipid fractions after extraction with 3 ml of chloroform/methanol/1 M HCl (6/3/1)^{5,6}.

thle methylation of phospholipids alters the membrane fluidity.

Previous work has shown that the enzymatic methylation of phosphatidylethanolamine has a low K_m for S-adenosyl-L-methionine (1.4 μ M), whereas the methylation of phosphatidyl-N-monomethylethanolamine to phosphatidylcholine had a high K_m for the methyl donor (0.1 mM)⁵. To determine whether synthesis of phosphatidyl-N-monomethylethanolamine and/or phosphatidylcholine was responsible for the changes in fluidity, varying concentrations of S-adenosyl-L-methionine were introduced into erythrocyte ghosts. Figure 2 shows the effects of increasing concentration of S-adenosyl-L-methionine on membrane viscosity. The concentration of S-adenosyl-L-methionine required for half-maximal reduction of the microviscosity was approximately 5 μ M. A plot of the amount of methyl group incorporated against S-adenosyl-L-methionine concentration shows an inflection point at about 25 μ M, indicating the presence of two enzymes in the methylation of phospholipids (Fig. 2). The identity of the methylated phospholipids at various concentrations of S-adenosyl-L-methionine were measured by introducing the methyl-³H labelled compound into the erythrocyte ghosts. When the methylated products were isolated and quantified using thin layer chromatography⁵, monomethylated phosphatidylethanolamine was found to form predominantly at concentrations of S-adenosyl-L-methionine below 25 μ M (Table 1). In these conditions, the membrane microviscosity reached nearly maximum. At concentrations above 25 μ M, phosphatidylcholine were increasingly formed (Table 1). These results indicate that the erythrocyte membrane fluidity changes are caused mainly by the enzymatic methylation of phosphatidylethanolamine to phosphatidyl-N-monomethylethanolamine. In contrast to phosphatidylethanolamine and phosphatidylcholine, we have found that phosphatidyl-N-monomethylethanolamine is deeply embedded in the erythrocyte membrane⁶. It is not susceptible to the digestion by phospholipase C from either the inside or outside erythrocyte ghosts. The accumulation of phosphatidyl-N-monomethylethanolamine within the lipid bilayer could account in greater part for changes of membrane fluidity.

Alterations in membrane fluidity due to phospholipid methylation should produce pleiotropic changes in membrane function. Preliminary results already indicate that binding of a catecholamine agonist with the β -adrenoceptor stimulates an increase of phospholipid methylation in reticulocytes and facilitates the lateral mobility and coupling of the receptor with adenylate cyclase (F. H., W. J. Strittmatter and J. A., unpublished).

We thank Drs M. H. Gottlieb and R. Aoshima, NIH, for their help and discussions in measurement of fluorescence.

Recognition and genetic control of helper determinants for cell surface antigen Thy-1

THE hapten-carrier effect in immune responses demonstrates that one antigenic determinant can strongly modulate the antibody response to a second determinant if the two exist in physical association. This phenomenon, in more general form termed associative recognition¹, has been analysed with soluble antigens and reveals collaboration between carrier-directed, helper T cells and hapten-directed, antibody-producing B cells. In contrast to soluble antigens, antibody responses to surface antigens of nucleated cells are poorly understood and although collaboration among T and B cells is indicated in several studies^{2–4} the antigenic sites recognised by these T cells and the extent of associative recognition among the different antigenic determinants on cell membranes is not known. Thus, it is not clear whether the determinants recognised by T and B cells are controlled by a single gene and are joined covalently or if the two determinants are controlled by independent genes and are only loosely associated or even unassociated on the cell surface. This knowledge would help determine the character and extent of molecular interactions on the surface of nucleated cells as well as principles of immunogenicity of antigens expressed on cell membranes. This report extends previous findings^{1,5} and describes a new experimental approach to study, in primary responses the role of alloantigens in the immunogenicity of Thy-1 through the use of closely related donor-recipient strains and an assay for antibody plaque-forming cells (PFC). The results are consistent with the notion that in primary immune responses Thy-1 is 'helpless' but that in appropriate donor strains, help may be supplied by other alloantigens controlled elsewhere in the donor genome.

To examine the contribution of other alloantigens to the immunogenicity of Thy-1 we immunised AKR/J (Thy-1.1) mice with thymus cells from AKR/Cum or CBA (both Thy-1.2). Since AKR/Cum is closely related to AKR/J^{6,7} differences between the immunogenicity of CBA and AKR/Cum cells could be attributed to alloantigens of CBA donors absent in AKR/Cum cells. CBA thymus cells induced a large anti-Thy-1.2 antibody response in AKR/J mice which was measured as numbers of direct PFC per spleen (Table 1). This response peaked at 7 d while AKR/Cum thymus cells induced few or no PFC at any time. The response is fully specific for Thy-1.1 determined as before⁸ and considered further below. Two possible reasons for this difference in immunogenicity apart from the contributions of other donor alloantigens were considered; first that AKR/Cum thymus cells express much less Thy-1.2 than CBA cells, was excluded in serological tests which showed them to be indistinguishable in the ability to absorb anti-Thy-1.2 antibody, and second that the Thy-1.2 antigen of AKR/Cum is suppressive, is unlikely since mixtures of CBA and AKR/Cum cells are immunogenic (data not shown) and since in a more rigorous control the antigen on (CBA $\times$ AKR/Cum) F_1 hybrid cells is highly immunogenic (Table 1).

The augmentative effect of alloantigens was further explored in other strain combinations and with cells having the reciprocal Thy-1 alloantigen. (CBA $\times$ AKR/Cum) F_1 mice were

immunised with thymus cells from strain AKR, (AKR × AKR/Cum) F_1 or (AKR × CBA) F_1 all of which produced few or no PFC in the recipients (Table 2). However, thymus cells from (AKR × B10.BR) F_1 mice were highly immunogenic. Each of the four donors can be shown to be immunogenic for Thy-1.1 in the appropriate recipients, however in the present experiment only the (AKR × B10.BR) F_1 cells contain numerous alloantigens to which the recipients are not genetically tolerant. Thus a Thy-1 incompatibility is insufficient to produce strong PFC responses and other alloantigens seem to augment Thy-1 immunogenicity. This result moreover demonstrates that in F_1 hybrid antigenic cells, chromosomes from one parent can control determinants which help the response to another antigen controlled by independent chromosomes from the other parent. These findings have been confirmed in a second strain pair (A/Thy-1.1 and A/Thy-1.2) in which large numbers of PFC were induced by A/Thy-1.1 cells in B10.A mice (H-2) compatible but otherwise allogeneic) but very few in congenic A/Thy-1.2 recipients.

A nonimmunological process may be proposed to explain the augmentative effects of an allogeneic haplotype, however this is unlikely. For example, it would be otherwise difficult to explain how the CBA donor haplotype augments the anti-Thy-1.2 response in AKR recipients to (CBA × AKR/Cum) F_1 (Table 1) but the same haplotype fails to augment the anti-Thy-1.1 response to (CBA × AKR) F_1 in (CBA × AKR/Cum) F_1 recipients (Table 2). The immunological basis of the effect is supported by evidence of thymus-dependency described below. Moreover, in a concurrent but more complex study of secondary PFC responses to Thy-1 in which reciprocal specificity controls are possible we have found the recognition of the non-Thy-1 helper determinants to be immunologically specific (E. A. Clark and P.L., unpublished).

In classical hapten-carrier systems it is held that these two antigenic components must be firmly associated for the haptenic determinant to be immunogenic; mixtures of molecules are not active⁹. To test if the Thy-1 determinant and the putative helper determinants need to be physically associated, (CBA × AKR/Cum) F_1 mice were immunised with two cell preparations. The first inoculum comprised (AKR × B10.BR) F_1 thymus cells which express both the B10.BR and the Thy-1.1 alloantigens on

Table 1 Weak primary response of AKR to Thy-1.2 alloantigen on closely related donor cells

Dose	Day	Donor strain/PFC per spleen (s.e.m.)		
		CBA(Thy-1.2)	AKR/Cum(Thy-1.2)	
4×10^7	3	39 (26)	0 (0)	
4×10^7	5	519 (237)	21 (19)	
4×10^7	7	2241 (252)	15 (8)	
4×10^7	9	270 (52)	90 (60)	
4×10^7	11	39 (10)	51 (18)	
		CBA	AKR/Cum	(CBA × AKR/Cum) F_1
8×10^7	7	3429 (861)	0 (0)	2,100 (542)
4×10^7	7	2,241 (252)	15 (9)	1,221 (258)
2×10^7	7	1269 (510)	30 (30)	909 (441)

Homogeneous pools of AKR mice (all mice were bred by ICRF) were arranged in groups of four and inoculated on the appropriate days i.v. with 4×10^7 donor thymus cells which has been washed three times in Eagle's minimal essential medium (MEM). Spleens were removed from all the recipients at one time and were individually dispersed with a loose fitting homogeniser in 10 ml of MEM supplemented with 10% heat-treated (56 °C, 30 min) newborn calf serum (CA₁₀). The spleen cells were centrifuged (800 r.p.m. for 10 min) and resuspended in 1.5 ml of MEM. Thymus cells were obtained from CBA mice aged 3 weeks, washed three times as above and resuspended at 10% v/v in MEM-CA₁₀. 50 μ l samples of the spleen cell suspensions were mixed with 20 μ l of the target thymus cells in 2 ml capacity plastic tubes at 37 °C and 180 μ l of 0.95% Agarose in MEM-CA₁₀ at 45 °C were added. The cell suspension was applied directly to a 35 mm plastic Petri dish, incubated, treated with complement and stained as described⁸.

Table 2 Immunogenicity of Thy-1 is helped by other donor alloantigens

Thymus donor	Thy-1 phenotype	Anti-Thy-1.1 PFC per spleen (s.e.m.)
AKR	Thy-1.1/1.1	75 (19)
(AKR × AKR/Cum) F_1	Thy-1.1/1.2	48 (7)
(AKR × CBA) F_1	Thy-1.1/1.2	0 (0)
(AKR × B10.BR) F_1	Thy-1.1/1.2	4,328 (680)

(CBA × AKR/Cum) F_1 mice which were age and sex matched were arranged in groups of five recipients each and were injected i.v. with 4×10^7 of the indicated cell suspension. PFC were determined after 7 d. No difference in immunogenicity of male and female donors was detectable in several controlled experiments and subsequently both donors were used.

each cell and the second was a mixture of B10.BR and AKR cells where the helper alloantigens and the Thy-1.1 determinants are on separate cells. It is evident from the results in Table 3 that the helper alloantigens must be expressed on the cells which carry the Thy-1 determinant for augmentation to result. Mixtures of cells fail to show any premium effect. This indicates that the Thy-1 antigenic determinant must be associated with the helper determinant in the same cell membrane for effective presentation to the immune system. It is unknown if this physical association of helper and Thy-1 represents linkage at the molecular level or if they are separate but joined by a membrane bridge. This observation differs fundamentally from the properties of helper sites controlled by the I-region which augment the induction of cytotoxic T cells¹⁰ in which help results, even when the two classes of antigen are expressed on separate cells. Taken together these studies indicate two pathways of antigen processing for T help to cellular antigens which are distinguished in their requirements for some form of structural association of the helper site and the determinant which is helped.

Stronger evidence for the immunological basis of the augmentation rendered by donor alloantigens was obtained by testing if this effect is thymus-dependent. From the results using 'B' mice (Table 3) it is apparent that this form of augmentation is thymus-dependent. The reduced overall magnitude of response is attributed to irradiation effects. The data also show that all the PFC detected on target cells of AKR produce specific anti-Thy-1.1 antibody since AKR/Cum target cells show no PFC.

Inbred strains of mice may differ for a multitude of alloantigens and those which are expressed on thymus cells are candidate helper determinants. Since it is known that structural associations between products of different genes can occur on the cell surface and that these intermolecular interactions are highly specific, for example between β_2 -microglobulin and H-2 or TL¹¹, it was possible therefore that help for Thy-1 was similarly associated with one or only a few select donor alloantigens controlled by their respective genes. To estimate the number of these genes, that is, of independently segregating genetic loci controlling the helper effect for Thy-1, a backcross experiment was done. A homogeneous population of AKR recipient mice was arranged into groups of two or three mice each and each group was inoculated with the thymus cells from individual (CBA × AKR/Cum) F_1 × AKR/Cum backcross progeny.

Since the F_1 hybrids are highly immunogenic it was expected that segregation of the helper loci of CBA would occur upon backcross mating the F_1 to the poorly immunogenic parent. Thymus cells from 76 backcross progeny mice of three weeks of age were injected into AKR recipients. Other recipients were injected with thymus cells from AKR/Cum and (CBA × AKR/Cum) F_1 donors which served as negative and positive controls respectively. Thus all donor mice were homozygous for the Thy-1.2 determining allele and segregants differed in their expression of putative helper alloantigens from the CBA parent.

The results in Fig. 1 show that the backcross progeny distribute into two categories of immunogenicity, those which fall into the zone of the poorly immunogenic AKR/Cum donors and those well above this zone and are thus augmented. Of 76 backcross mice, 23.7% (18 mice) were of the low immunogen type and 76.3% (58 mice) were augmented immunogens as compared with controls. This result is statistically consistent with the presence of two unlinked chromosomal loci in the donor CBA genome, each capable of augmenting in antigenic thymus cells the immunogenicity of Thy-1.2 for primary antibody responses (chi-square test $0.95 < P < 0.90$). The scattergram also suggests that the two 'helper loci' may differ in strength and that their representative genes are fully penetrant and dominant or codominant. It is unknown if the determinants which help the Thy-1 response are exclusive in their effect to Thy-1 or if they can also help other surface antigens. The identification of the helper determinants and their properties is therefore important to pursue.

There are indications that similar associative recognition phenomena may apply to responses to other surface antigens. In a recent study it was shown that, even subsequent to extraction and purification, a potent carrier effect of one cell surface molecule for another with which it natively associates on the cell membrane is preserved¹². The requirement for help of one surface antigen from other antigens may explain why most congenic immunisation regimens fail to produce anti-Ly antibodies¹³ as well as the absence of IgG production in a congenic H-2 immunisation¹⁴. In successful congenic immunisations the response may be more thymus-independent^{2,3} or alternatively obtain T cell help from antigens coded for by closely-linked genes. There is also evidence that some helper determinants may themselves be latent and are immunogenic only in the presence of other antigens¹⁵.

In summary the results show that the Thy-1 antigen is much more immunogenic if presented on donor cells which also carry other alloantigens and that this helper effect is thymus-dependent. These helper sites and the Thy-1 antigen must be expressed on the same cell surface and not on separate cells, indicating

Table 3 Evidence that helper alloantigens must be on the cells expressing the determinants which are helped and thymus-dependence of the effect

Expt 1		Anti-Thy-1.1 PFC per spleen (s.e.m.)
Thymus donor	Thy-1 phenotype	
AKR	Thy-1.1/1.1	345 (127)
B10.BR	Thy-1.2/1.2	0 (0)
(AKR×B10.BR)F ₁	Thy-1.1/1.2	4,554 (425)
AKR+B10.BR ^a	Thy-1.1/1.1	387 (72)
	+Thy-1.2/1.2	
AKR+B10.BR ^b	Thy-1.1/1.1	186 (36)
	+Thy-1.2/1.2	
Expt 2		Anti-Thy-1.1 PFC per spleen (s.e.m.)
Thymus donor	Pre-irradiation treatment	
AKR+B10.BR	Thymectomy	54 (71)
(AKR×B10.BR)F ₁	Thymectomy	9 (20)
AKR+B10.BR	Sham thymectomy	33 (22)
(AKR×B10.BR)F ₁	Sham thymectomy	*753 (252)

(AKR/Cum×CBA)F₁ mice, in groups of five recipients each, were injected i.v. with 4×10^7 of the indicated cell suspension except for the cell mixture where in (a) 8×10^7 cells were injected and in (b) 4×10^7 cells were injected. Cells were mixed in a 1:1 ratio. PFC were determined after 7 d. In Experiment 2 (CBA×AKR/Cum)F₁ mice were thymectomised or manipulated surgically but not thymectomised. After a recovery interval of 3 weeks all mice were given 750 rad of γ -irradiation and 5×10^6 fetal liver cells from syngeneic mice. The mice were used after an additional 5-week period.

* Portions of these spleens (1/30) were tested on AKR/Cum target and no PFC were detectable.

Fig. 1 Distribution of immunogenicity of thymus cells from individual backcross mice with segregating helper determinants. Evidence for two antigenic 'helper genes'. A large age-matched pool of AKR female mice was randomised and arranged in groups of two or three recipients per backcross donor thymus and in groups of five or six for control thymus suspensions (a pool of several donors). The recipients were immunised with 4×10^7 (CBA×AKR/Cum)F₁×AKR/Cum backcross thymus cells i.v. and PFC per spleen determined on day 7. Each point represents the mean PFC per spleen of two or three recipients. Vertical bars represent ± 1 s.e.m.

that some form of physical bridge between Thy-1 and its helper is important in the presentation of the surface antigen to the immune system similar to hapten-carrier antigens. Further, we have shown that highly effective helper sites are controlled by chromosomes lacking the relevant Thy-1 antigen and the data suggest that only two genetic loci control these helpers in primary antibody responses.

We thank Professor N. A. Mitchison, and Drs M. Baltz and P. Golstein for discussions and J. Bromberg for reconstituted mice. P.L. was supported by the MRC of Canada and an ICRF Fellowship and T.D. by the Basel Institute for Immunology and the Medical Genetics Center.

Adenylate cyclase in a fibroblast mutant defective in glycolipid and glycoprotein synthesis

THERE is currently wide interest in the biological role of glycolipids and glycoproteins of the cell membrane. As some transformed cells have reduced levels of the more complex gangliosides and neutral glycolipids (see refs 1–3 for reviews), it has been suggested that complex gangliosides and particularly ganglioside G_{M1} may have an important role in regulating cell growth and in the responsiveness of adenylate cyclase (ATP pyrophosphate-lyase (cyclising), EC 4.6.1.1) to regulatory factors^{3,4}. The ganglioside G_{M1} is thought to be required for the activation of plasma membrane adenylate cyclase by cholera toxin; the toxin activates adenylate cyclase⁵ and binds specifically to ganglioside G_{M1} (refs 6–8). To investigate the effect of altered glycolipid and glycoprotein composition on adenylate cyclase activity we have used cell line AD6, a mutant of BALB/c 3T3 cells that is deficient in glucosamine phosphate acetyl transferase^{9–12}, and therefore partially blocked in its ability to synthesise complex carbohydrates, glycoproteins and glycolipids. Our results show that AD6 cells have a decreased responsiveness to cholera toxin, indicative of an altered membrane ganglioside composition, yet the responses of the enzyme to GTP, adrenaline, prostaglandin E_1 and fluoride are unaltered. Our results indicate that decreased synthesis of complex gangliosides does not result in alterations in adenylate cyclase other than a decreased response to cholera toxin.

For the present studies cells were grown in Dulbecco–Vogt's modified Eagle's medium supplemented with 10% calf serum (Colorado Serum) as described by Pouyssegur and Pastan⁹. For the determination of cholera toxin activation of adenylate cyclase cells were changed to serum-free medium 12 h before addition of cholera toxin. Cells were then incubated with the indicated concentration of cholera toxin (Schwarz-Mann) for 3 h

Fig. 1 Effect of cholera toxin treatment of intact Swiss 3T3 (●), BALB/c 3T3 (Δ), SV40-BALB (○), or AD6 (▲) cells on adenylate cyclase activity measured in a crude membrane fraction prepared from the indicated cell type. Cells were changed to serum-free Dulbecco–Vogt modified Eagle's medium and incubated with the indicated concentration of cholera toxin for 3 h before determination of adenylate cyclase activity. Enzyme activity was measured as described¹³ with 0.2 mM ATP, 3 mM Mg^{2+} and 1 mM EGTA.

Fig. 2 Effect of G_{M1} on cholera toxin activation of adenylate cyclase in wild-type BALB/c 3T3 (a) or AD6 cells (b). Cells were incubated for 18 h in serum-free medium with (closed symbols) or without (open symbols) 50 pmol G_{M1} per dish, then washed three times with phosphate-buffered saline and once with serum-free growth media. Cells were then incubated in serum-free media with the indicated concentration of cholera toxin for 3 h before determination of adenylate cyclase activity as described in Fig. 1.

before collection. A crude membrane fraction was prepared and adenylate cyclase activity measured as described elsewhere¹³. Triplicate determinations of adenylate cyclase activity were routinely within $\pm 10\%$.

The block in the formation of *N*-acetylglucosamine and derived amino sugars would be expected to lead to decreased synthesis of the more complex gangliosides from ganglioside G_{M3} (see the pathway for ganglioside biosynthesis presented in ref. 3) as well as glycoproteins. From published data^{14,15} it is established that Swiss 3T3 cells have higher levels of the complex gangliosides than do BALB/c 3T3 cells, and SV40-transformed cells have very low or undetectable amounts of G_{M1} and G_{D1a} . Data in Fig. 1 show that incubation of intact cells for 3 h with cholera toxin markedly enhances basal adenylate cyclase activity. Swiss 3T3 cells which contain more of the complex gangliosides are more sensitive to cholera toxin activation presumably due to G_{M1} functioning as the toxin receptor. AD6 cells have a reduced response to cholera toxin. This result suggests that AD6 ganglioside levels are comparable to the SV40-transformed cells.

A chemically transformed line of mouse fibroblasts has been described which lacked G_{M1} and was unresponsive to cholera toxin (ref. 16). When incubated in medium containing G_{M1} , these cells bound the ganglioside and responded to cholera toxin as measured by activation of adenylate cyclase and elevation of cellular cyclic AMP content^{16,17}. To determine if the incorporation of G_{M1} into AD6 or wild-type BALB/c 3T3 cells would improve the response to cholera toxin, confluent cells were changed to serum-free growth medium and incubated with 50 or 500 pmol G_{M1} per dish (100 mm dish containing 5 ml growth media) for 12 h. The ability of cholera toxin to enhance adenylate cyclase activity was determined as described in Fig. 2. A few of the cells (<15%) detached from the substratum during incubation in serum-free medium; only those cells remaining on the dish were used to determine cholera toxin responsiveness. When AD6 cells were treated with 50 or 500 pmol G_{M1} per dish, a significant increase in cholera toxin activation was observed (Fig. 2). Thus, the incorporation of G_{M1} into the mutant membrane corrects the inability of cholera toxin to activate adenylate cyclase of the mutant to the same extent as observed with the wild-type parent. Similar treatment of the BALB/c 3T3 parent did not result in further stimulation by cholera toxin.

Fig. 3 Effect of *N*-acetylglucosamine on cholera toxin activation of adenylate cyclase in AD6 cells. Cells were grown to confluence in the presence (●) or absence (○) of 10 mM *N*-acetylglucosamine. Addition of the indicated concentration of cholera toxin and determination of enzyme activity were carried out as described in Fig. 1.

Keenan *et al.*¹⁸ have suggested that artificially supplied gangliosides assume a configuration or localisation in the membrane different from that of the native ganglioside. Nevertheless, the results of Fig. 2 show that sufficient ganglioside G_{M1} molecules become associated with the cell surface to serve as receptors for cholera toxin. In addition to showing that ganglioside G_{M1} may act as a cholera toxin receptor, these results emphasise that the low cholera toxin response observed in AD6 cells is due to a decreased ability to recognise and bind cholera toxin.

Previous studies have demonstrated that when AD6 cells are grown with *N*-acetylglucosamine the defect in the *N*-acetylation of glucosamine-6-phosphate is bypassed and the mutant cells revert to the wild-type phenotype^{10,11}. When AD6 cells were grown with 10 mM *N*-acetylglucosamine, the ability of cholera toxin to stimulate adenylate cyclase was enhanced (Fig. 3). This result, together with the ability of exogenous G_{M1} to increase cholera toxin activation of adenylate cyclase in AD6, indicate that it is the altered carbohydrate composition of the plasma membrane of AD6 cells that accounts for their decreased sensitivity to cholera toxin. As AD6 cells have normal growth

Table 1 Adenylate cyclase activities of wild-type, AD6 and transformed BALB/c 3T3 cells

Addition	Wild-type BALB/c 3T3	Adenylate cyclase activity		
		AD6	Kirsten- BALB	SV40- BALB
	cyclic AMP (pmol formed per 10 min per mg protein)			
None	31 ± 4	25 ± 3	92 ± 6	101 ± 6
GTP	35 ± 4	29 ± 4	272 ± 9	319 ± 15
GTP + L-adrenaline	378 ± 17	336 ± 20	269 ± 14	346 ± 16
GTP + PGE ₁	89 ± 7	69 ± 7	295 ± 21	352 ± 29
Fluoride	521 ± 27	452 ± 31	1052 ± 46	1138 ± 22

Adenylate cyclase activity was measured as described elsewhere¹³ with 0.2 mM ATP, 3 mM MgCl₂, 1 mM EGTA, and 10 μM GTP, 10 μM L-adrenaline, 10 μg ml⁻¹ prostaglandin E₁ or 10 mM NaF as indicated. A crude membrane preparation of each cell type was used as the source of enzyme. Values presented are the mean ± S.E. for duplicate and triplicate determinations.

properties, this result also indicates that the decreased ganglioside content found in some transformed cells is not by itself a primary cause of the transformed state.

In studies with several virally transformed fibroblast lines a defective adenylate cyclase system has been observed^{19,20}. It is evident from the results presented in Table 1 that BALB 3T3 cells transformed by either the Kirsten sarcoma virus or SV40 virus have elevated basal, GTP-stimulated and fluoride-stimulated adenylate cyclase activities and a decreased or absent response to hormonal activation. Yet, with AD6 cells the adenylate cyclase activity was fully responsive to hormonal stimulation. This result tends to suggest that changes in membrane structure other than modification of the carbohydrate moieties are responsible for the altered properties of adenylate cyclase noted with transformation.

The mutant cell AD6 used in this study has also been found to have decreased binding of epidermal growth factor, presumably because its receptor is a glycoprotein²¹. The use of mutants with defined defects such as AD6 should help elucidate the role of glycolipids, glycoproteins and other complex molecules in cell behaviour.

Release of acetylcholinesterase from rat hemidiaphragm preparations stimulated through the phrenic nerve

ACETYLCHOLINESTERASE (AChE; EC 3.1.1.7) is known to be transported rapidly within peripheral motor nerves, both towards and away from nerve cell bodies^{1–3}. Of the total amount of neural AChE, approximately 15% is mobile, with about 10% moving towards the nerve terminals and about 5% returning towards cell bodies, the remaining 85% of the enzyme being stationary. Since the mean velocity of orthograde transport is about twice that of the retrograde flow, the total flux of enzyme is 3–4 times greater in the distal than in the proximal direction. Although the fate of this transported

AChE is not entirely clear, it has recently been shown that some of the distally transported enzyme may never arrive at the nerve terminals, being incorporated into the axolemma at sites all along the neurone^{4,5}. This axolemmal incorporation is slow, and it seems likely that AChE would accumulate in the terminals unless there were local mechanisms for its removal, such as proteolytic digestion or extrusion from the cell as has been demonstrated in non-neuronal tissue^{6,7}. We now offer evidence that AChE is released from nerve terminals in response to nerve stimulation and suggest that this release may be parallel to, but separate from, release of neurotransmitter.

Isolated rat phrenic nerve-hemidiaphragm preparations were incubated at 37°C in beakers each containing 1 ml of oxygenated physiological saline solution with (+)-tubocurarine (1.4×10^{-5} M) added to prevent muscle contraction. Preparations were equilibrated in this solution for 1 h, followed by three 15-min incubation periods. At the end of each incubation period, preparations were transferred to new beakers containing fresh medium. The media exposed to tissue during experimental periods were chilled to -20°C immediately after collection and were subsequently analysed for their AChE content by the radiometric assay of Potter⁸. Resting release of AChE was determined from the enzyme activity in the media collected after the first and second experimental periods. This activity averaged 39.2 ± 1.5 nmol of acetylcholine (ACh) hydrolysed per h per ml of medium (mean $\pm$ s.e.m., $n=98$). During the third experimental period, the phrenic nerve was gently lifted out of the bathing medium and stimulated through platinum electrodes with supramaximal 5-V square-wave pulses of 0.4 ms duration and at frequencies of 0–200 Hz. The nerve was positioned such that the oxygenation of the bath splashed medium on the nerve and kept it moist during the stimulation period. To determine the effects of stimulation, resting release (mean activity collected during the first two experimental periods) was subtracted from the activity accumulating during the third period of each experiment. Release from preparations not stimulated during the third period was essentially identical to resting release, whereas stimulation increased the release of AChE in a frequency-related manner (Fig. 1). Stimulation-induced release was statistically significant at 0.2 Hz and highly significant at frequencies of 2 Hz or above, even though the maximum release (at 200 Hz) was only 32% above basal levels (Fig. 1). Since the concentration of (+)-tubocurarine used in these experiments

totally prevented muscle contractions, and has been shown to eliminate muscle action potentials in response to nerve stimulation⁹, it is unlikely that the AChE released from our stimulated preparations arose from the muscle. In two experiments in which we incubated 2-cm lengths of phrenic nerve from which the diaphragm had been removed by a cut close to the muscle, we could detect neither resting release nor release in response to 20-Hz stimulation. We infer from these data that little or no AChE was extruded from non-terminal axons.

Low Ca^{2+} -high Mg^{2+} solutions have been shown to inhibit nerve-stimulated release of the neurotransmitter ACh^{10,11}. In our experiments, resting release of AChE was somewhat reduced in the presence of low Ca^{2+} and high Mg^{2+} (mean = 18.1 ± 1.7) and nerve-stimulated release of AChE at a frequency of 0.2 Hz was completely inhibited (Fig. 1). Although these results suggest a similarity between ACh release and AChE release, there is one important difference. The latter was found to be frequency related up to 200 Hz, whereas ACh release has been reported not to be related to frequency beyond 25 Hz¹². It therefore seems unlikely that the enzyme is extruded from the same sites or by the same mechanism as the neurotransmitter.

Fig. 2 Velocity sedimentation profile of AChE activity from phrenic nerve-hemidiaphragm effluent. The bathing media of nerve-muscle preparations were layered on 4.8 ml density gradients of 10–40% (w/v) sucrose containing 1 M NaCl, 0.2 mM EDTA, 50 mM Tris-HCl (pH 7.4) and 1% Triton X-100, and were centrifuged at 58,000 r.p.m. for 16 h in an SW65 rotor in an L2 65B ultracentrifuge. AChE activity from resting (●) and 2.0 Hz nerve-stimulated (○) preparations was assayed as described and corrected for effects of the sucrose. Marker proteins used to calibrate the gradients were 16S β -galactosidase (Z); 11.2S catalase (C); and 4.4S bovine serum albumin (B). AChE activity in the 10S (fractions 9–13) and 4S (fractions 16–20) peaks of nerve-stimulated preparations differed significantly ($P < 0.05$) from the corresponding peaks in the resting state as determined by a paired t -test. The values represent the means of four nerve-muscle preparations for both resting and nerve-stimulated tissues.

Fig. 1 Release of AChE from nerve-stimulated rat phrenic nerve-hemidiaphragm preparations. Tissues were incubated in isotonic buffer of the following composition (mM): NaCl, 115.0; KCl, 5.0; CaCl_2 , 2.5; MgCl_2 , 0.5; glucose, 5.0; sucrose, 24.0; HEPES (pH 7.4), 15.0; bovine serum albumin, 0.2%. Low Ca^{2+} -high Mg^{2+} buffer differed in the following constituents: CaCl_2 , 0; MgCl_2 , 10.0; sucrose, 3.0. Accumulations of AChE in response to nerve stimulation represent activity in excess of the resting release of enzyme (see text). Mean values and s.e.m. are shown. Significance levels, determined by Student's t -test, are: * $P < 0.05$ at 0 Hz; ** $P < 0.005$ at 0 Hz; *** $P < 0.001$ at 0.2 Hz in normal buffer. A least squares regression analysis showed a significant linear relationship between release of AChE and log frequency over the range 0.02–200 Hz (slope = 1.46 ± 0.58 , $P < 0.02$).

Three isozymes of AChE have been identified in mammalian muscle and nerve, having sedimentation coefficients of approximately 4S, 10S and 16S (refs 13–15). We studied the molecular forms of AChE released into the bathing medium by resting and stimulated nerve-muscle preparations. Tissues were incubated as described above; however, to concentrate the enzyme, the volume was reduced to 0.5 ml and the collection periods were increased to 30 min. Aliquots (0.2 ml) of bathing medium were layered on to sucrose density gradients, centrifuged, fractionated from the bottom of the tube, and assayed for AChE (Fig. 2). The media collected from resting preparations were found to contain both 4S and 10S enzyme, but about three times more of the latter than of the former. Both forms of AChE were released by stimulation, but more than 80% of the released enzyme sedimented at 10S. No 16S AChE was detected in media from resting or stimulated preparations.

The distribution of molecular forms of AChE released into the bathing media from our nerve-muscle preparations does not resemble the distribution in muscle, which contains significant amounts of 16S enzyme, primarily in the endplate

regions, and approximately equal amounts of 10S and 4S enzyme^{13,14}. The distribution of released forms of AChE is, however, similar to the distribution in nervous tissue^{13,15} and resembles especially closely the distribution of forms carried distally by rapid transport along peripheral nerve axons¹⁵. These results suggest not only that the AChE released following nerve stimulation derives from the nerve terminal, but that much of the resting release of AChE also comes from nerves rather than from muscle.

Several investigators have demonstrated that substances other than neurotransmitters may be released from motor nerves on electrical stimulation. Amino acids¹⁶, as well as proteins^{17,18} presumably transported distally from cell bodies, are released from nerve terminals. Although AChE has not previously been identified as being released from nerve-muscle preparations, it has been shown to be released from cultured chick embryo spinal cord cells¹⁹ and from adrenal glands bathed in high potassium solutions^{20,21}. In the latter case, the release was shown to depend on calcium and was believed to arise, at least partly, from splanchnic nerves²¹.

The content of AChE in muscle is influenced, in part, by the motor neurone²²⁻²⁴. This has been demonstrated convincingly by the reduction of AChE activity in denervated muscle. Although denervated muscle is still capable of synthesising AChE, the enzyme levels never reach those of innervated controls²⁵. In addition, blockade of axonal transport in motor nerves with colchicine has produced denervation-like changes in the AChE content of muscles without interrupting neuromuscular transmission²³. These results suggest that muscle AChE is partially regulated by substances that are transported down the nerve and are released from the nerve terminals.

Our results do not exclude the possibility that one of these regulatory substances is AChE itself. The enzyme has not been demonstrated to be associated with synaptic vesicles, but has been shown to be localised in cisternae of smooth endoplasmic reticulum (SER) in nerves²¹. We suggest that these cisternae may release their contents when action potentials invade the nerve terminals. The mechanism of this release could share features in common with the exocytotic release of neurotransmitter from the synaptic vesicles. In any case, if the released AChE were able to diffuse across the synaptic cleft, it might be responsible for some of the trophic effects of nerves on muscle and could even serve as one source of muscle AChE.

Evidence for two separate opiate peptide neuronal systems

WHEN Hughes *et al.*¹ first described the sequences of the enkephalins, they pointed out that methionine-enkephalin (met-enkephalin) could be found in β -lipotropin (β -LPH 61-65). The entire C-terminal fragment of β -LPH was subsequently found to have opiate-like properties (β -LPH 61-91 or β -endorphin)²⁻⁷, and it seemed reasonable to hypothesise that the primary biosynthetic route for met-enkephalin was β -LPH to β -endorphin and eventually to met-enkephalin. Although this hypothesis awaits biochemical evidence, immunocytochemical studies of these peptides may shed light on the question. If β -LPH and β -endorphin are, in fact, enkephalin precursors which are stored by enkephalinergic neurones, one would expect them to be visualised in met-enkephalin-positive cells. Several laboratories produced immunocytochemical maps of the distribution of enkephalin-like-immunoreactivity (enkephalin-reactivity) in mammalian brain⁸⁻¹¹. Watson *et al.*¹² demonstrated β -LPH-reactive cells and processes in rat brain. This β -LPH reactivity has the same distribution as β -endorphin-like-immunoreactivity (β -endorphin-reactivity) as reported by Bloom *et al.*¹³ and Watson *et al.*¹⁴. However, the distribution of the β -LPH/ β -endorphin-reactive system on the one hand and the met-enkephalin-reactive system on the other seemed quite different. Met-enkephalin-reactivity was seen in many local cell groups throughout the neuraxis, especially the lower brain stem⁸⁻¹¹, whereas β -LPH- and β -endorphin-reactivities were found only in a single hypothalamic cell group with long ascending and descending processes¹²⁻¹⁴. We present here biochemical and anatomical evidence for the existence of two separate opioid systems in brain—an enkephalin system and a β -LPH/ β -endorphin system. We also present immunocytochemical data for the coexistence in the brain of ACTH with β -LPH/ β -endorphin.

The investigation of the coexistence of ACTH with β -LPH is based on evidence from the pituitary where β -LPH and β -endorphin have been localised in the corticotrophs^{15,16}, in fact, within the same granules¹⁷. These two pituitary peptides possess a common precursor of molecular weight, 31,000 as demonstrated in cell cultures¹⁸, and, in the intact rat, are co-released into the plasma upon stress¹⁹. Such evidence, coupled with the biochemical and immunocytochemical demonstration in brain of β -LPH (refs 12, 20, 21) and of ACTH (refs 22, 23), has led us to investigate whether the same relationship between ACTH and β -LPH/ β -endorphin exists in brain as it does in the pituitary.

Because the present studies depend primarily on the use of multiple antibodies with unique cross-reactivities, the following is a summary of their characteristics. Four antisera were used: anti-methionine-enkephalin (our laboratory), anti- β -LPH (from C. H. Li) anti-ACTH and anti- β -endorphin (R. Mains/B. Eipper). Cross-reactivity of these antisera was tested both in radioimmunoassay (RIA) and immunocytochemical systems by classical competition methods. The met-enkephalin antibody has been described elsewhere²⁴. It exhibits no cross-reactivity with β -LPH, β -endorphin, ACTH or β -melanocyte stimulating hormone (β -MSH). Its cross-reactivity with leu-enkephalin is less than 1:200 and with α -endorphin less than 1:250. ACTH antibody was affinity-purified using ACTH 1-24 (ref. 25) and has been shown to be directed against ACTH 11-24. It does not cross-react with β -LPH, β -endorphin, or

their smaller fragments (β -MSH and met-enkephalin). β -Endorphin antiserum is directed against α -endorphin (β -LPH 61-76). It cross-reacts with β -endorphin and with the full β -LPH molecule on an equimolar basis. It does not, however, cross-react with met-enkephalin, ACTH or β -MSH. β -LPH antiserum seems to be primarily directed at the N-terminus of the β -LPH molecule, as it recognises β -LPH (1-41) and does not recognise β -MSH (β -LPH 41-58)^{26,27}. In the conditions of our RIA this antiserum exhibits very low cross-reactivity with β -endorphin (less than 1:100) with a very shallow dilution curve. In fact, we cannot obtain more than 10% inhibition of binding with concentrations of β -endorphin at 100 nM, whereas β -LPH causes 10% inhibition at 0.05 nM. We have carried out extractions of rat pituitary and brain which are optimal for β -LPH with little contamination with β -endorphin. The β -LPH antiserum demonstrates activity against these ' β -LPH extracts'. The dilution curves are not parallel to those of β -endorphin in this RIA, suggesting that we are not measuring the C-fragment of β -LPH, but possibly its N-terminus. It should be noted, however, that β -LPH N-terminus varies with phylogeny and has not been sequenced in the rat.

Finally, some of the immunocytochemical studies using β -LPH antiserum were carried out in the presence of excess β -endorphin (1 μ M) and the results were unaltered. In contrast, the addition in much lower concentrations of β -LPH (5 nM) led to complete blockade of the anatomical demonstration. The low cross-reactivity of this antiserum with β -endorphin, the different slopes of dilution curves and the lack of blockade by β -endorphin in anatomical studies suggest that we are looking primarily at the N-terminus of β -LPH, and that the cross-reactivity with C-fragment is due to a small sub-population of antibody.

Thus, three of the antisera used in our studies apparently recognise three different aspects of the precursor molecule; that is, ACTH, the N-terminus of β -LPH, and β -endorphin (or C-terminus of β -LPH). A positive response of all three within the same system might indicate the existence within that system of either precursor or of its individual components.

The evidence for two separable opioid systems is derived from both anatomical observations and a lesion study. As mentioned above, only one hypothalamic cell group combines β -LPH and β -endorphin reactivity, whereas met-enkephalin-positive cells can be visualised in several regions throughout the brain stem but not in the β -LPH/ β -endorphin-containing hypothalamic group. Furthermore, some brain areas are rich in met-enkephalin axons and terminals (for example, globus pallidus), but are almost totally devoid of β -LPH/ β -endorphin activity.

To ascertain that these differential distributions are not due to any artefact of visualisation, we have devised a technique for extracting β -LPH and the enkephalins from the same tissue^{21,28}. As the structure of β -LPH in the rat is unknown, and as our extract dilution curves differ in slope from the human β -LPH curve, all values are expressed in units as described in Table 1. Using the β -LPH and met-enkephalin RIAs, we obtain very different distributions of the two peptides in various brain regions. Again, the striatum has the highest concentration of met-enkephalin in the brain (1,750 pmoles per g wet weight), but β -LPH levels in the striatum (1 unit per g) are about 10-fold lower than in the hypothalamus (9-10 units per g) and are exceeded by levels in the central grey and thalamus (2.5 units per g).

We therefore reasoned that if the two systems are in fact separate, specific lesions may be able to differentiate between them. We produced unilateral lesions of the basal hypothalamus arranged so as to destroy the majority of the β -LPH-positive cells ($n=5$). The control group was sham operated ($n=5$). Ten days after surgery, the animals were killed, their brains rapidly removed and the cortex, septum, cerebellum and hippocampus dissected away. The remainder of the brain was divided into a posterior region containing the medulla-pons, central grey, tegmentum and colliculi, and an anterior region

Table 1 Effect of unilateral hypothalamic lesions on met-enkephalin and β -LPH in two regions

	Enkephalin (pmol per g tissue) Met-enkephalin	β -LPH: (units per g) β -LPH
Posterior region	Controls = 1,110 $\pm$ 193 Lesioned = 890 $\pm$ 230 %C = 80% Not significant	Controls = 5.0 $\pm$ 0.4 Lesioned = 2.3 $\pm$ 0.8 %C = 45% $P < 0.02$
Anterior region	Controls = 1,431 $\pm$ 85 Lesioned = 1,159 $\pm$ 165 %C = 81% Not significant	Controls = 2.5 $\pm$ 0.4 Lesioned = <1.2 %C = <50%

Lesions were placed in the basal hypothalamus unilaterally to destroy β -LPH cells. Brains were rapidly removed, dissected, frozen and homogenised with 0.4 M PCA. The supernatant contained met-enkephalin and the pellet β -LPH which were assayed by specific RIAs. The anterior region includes hypothalamus, thalamus and striatum. The posterior region includes central grey, medulla pons, tegmentum and colliculi. As lesions are unilateral, a 50% drop could indicate complete loss on one side (see text). A similar study of a lesion in the periaqueductal central grey produced major changes in met-enkephalin with minor changes in β -LPH levels. β -LPH values are expressed in units. This is necessary because the dilution curve of rat extracts is not parallel to human β -LPH standards. The quantitation is carried out in terms of a dilution curve of pituitary rat extract. At 50% inhibition, 1 unit corresponds to 1 pmol of human β -LPH.

involving thalamus, hypothalamus and striatum. The brains were rapidly frozen on dry ice, and β -LPH and enkephalin were extracted using 0.4 M perchloric acid as described elsewhere^{21,28}. Table 1 shows the results of β -LPH and enkephalin RIAs. As can be seen, β -LPH levels decreased significantly to about 50% of control, a maximal drop for a unilateral lesion. On the other hand, met-enkephalin levels showed a lower drop which did not reach significance in either brain part. It is important to note that such a differential effect cannot be attributed to differences in the turnover rates of the two substances, because in similar conditions lesions in the mesencephalic central grey produce the opposite pattern (that is, a significant decrease in enkephalin and no change in β -LPH levels in the anterior region)^{21,28}. The sites of lesions in these studies were immunohistologically confirmed in a separate group of animals.

As the above studies suggested the separability of β -LPH/ β -endorphin from the enkephalin systems, we proceeded to characterise the endorphin system further. Using the above antisera, we have studied the anatomical distribution of β -LPH, β -endorphin and ACTH in the same section of rat brain.

Male Sprague-Dawley rats were injected intracerebroventricularly with 50 μ g colchicine in 50 μ l of saline 48 h before death. Sections were prepared for immunocytochemistry as described elsewhere^{8,9}. Briefly, the rats were perfused with 4 g per 100 ml formaldehyde, their brains removed and blocked, re-exposed to formaldehyde solution followed by 10 g per 100 ml sucrose phosphate-buffered saline (PBS), frozen in liquid nitrogen and then sectioned in a -20°C cryostat. 10- μ m sections were incubated for 48 h with rabbit anti-ACTH antibody (1/1,500). They were washed and exposed to goat anti-rabbit-fluorescein isothiocyanate (FITC) tagged IgG (1/80), rewashed, viewed and photographed with a Leitz Orthoplan microscope. The sections then had their coverslips removed, were washed and exposed to 6 M guanidine HCl overnight (to break antigen-antibody bonds); their coverslips were then replaced, and they were viewed again. The areas photographed earlier were exposed to ultraviolet (UV) light until the residual fluorescence was completely exhausted, and then rephotographed. The section was washed again, and incubated with goat anti-rabbit IgG (without FITC) to block any remaining rabbit anti-ACTH antibody which had not been removed by guanidine HCl. The section was then exposed to the second antibody (β -endorphin) and the entire sequence repeated. The

third antibody (β -LPH) was visualised in the same way. Thus, exactly the same area could be studied for immunoreactivity to ACTH, β -endorphin and β -LPH.

All three antisera could be blocked by 1 μ M of the appropriate peptide. Several sections were run to demonstrate that goat anti-rabbit-FITC did not rebind to residual primary antibody, that guanidine HCl did not damage the immunoreactivity of these three peptides, that after guanidine HCl an antigen could be revisualised, and that guanidine treatment is not necessary for the demonstration of the second or third antigen. Further, some animals were run without colchicine to ascertain that this drug did not alter the pattern of immunoreactivities. These sections showed the same results, although cell body fluorescence was less intense.

Sections through the periaruate region of the hypothalamus were studied because cells for all three peptides (ACTH, β -LPH and β -endorphin) were found only in this area. Figure 1 shows the ACTH-positive (1a), β -endorphin-positive (1b) and β -LPH-positive (1c) cells in the arcuate region. All three antisera demonstrated the same cells and fibres. We observed no cells which contained one peptide and not the others. Fibres in the hypothalamus, medial amygdala and periventricular nucleus of the thalamus exhibited the same pattern for all three antisera. Fluorescence was absent in peptide-blocked (1 μ M) controls taken from serial sections (not shown). We have not yet seen any overlap between cells positive for the enkephalin system and those positive for ACTH/ β -LPH/ β -endorphin.

Fig. 1 Immunocytochemical demonstration of ACTH, β -endorphin and β -lipotropin immunoreactivity in the same hypothalamic neurones. Adult male Sprague-Dawley rats given 50 mg colchicine intracerebroventricularly, 48 h earlier; prepared for immunocytochemistry as in text. *a*, ACTH-positive cells in the periaruate region of hypothalamus (see arrows). Magnification $\times 200$. Fluorescence was completely lost after exposure to 6 M guanidine HCl and UV light. *b*, The same section, after exposure to 6 M guanidine HCl and UV light, was re-exposed to goat anti-rabbit IgG to block remaining rabbit IgG. It was then exposed to β -endorphin antiserum. The same cells are revisualised (see arrows). Magnification $\times 200$. Again, exposure to 6 M guanidine HCl and UV light eradicated fluorescence. *c*, Re-exposure to goat anti-rabbit IgG as in *b*, followed by incubation with β -LPH antiserum. The same cells and processes are seen in all three photographs. Excess peptide (1 μ M) blocked all fluorescence.

Using anatomical, biochemical and immunological tools, it has been possible to demonstrate the existence of two separate opiate peptide neuronal systems, one being an enkephalin system and the other a β -LPH/ β -endorphin/ACTH-positive system. During this work, Rossier *et al.*²⁹ reported that β -endorphin and enkephalin, as measured by RIA, are located in different proportions in several brain regions, again supporting the hypothesis of two separate opiate peptide systems. Although it is possible that β -endorphin serves as a precursor for met-enkephalin in enkephalin cells, it is also likely that it functions as a neuroregulator in its own neuronal pool. Further, it seems unlikely that met-enkephalin is purely a breakdown product of β -endorphin, as these peptides occur in morphologically separate systems and can be differentially altered by lesions. The relationships between these two neuronal-biochemical systems and between the peptides within each system remain to be determined.

We thank Dr C. H. Li for β -LPH and anti- β -LPH antiserum, Drs R. Mains and B. Eipper for anti-ACTH and anti- β -endorphin antisera and Ciba-Geigy for synthetic ACTH 1-24. The role of GABA in the substantia nigra

STRIATONIGRAL GABAergic fibres are widely believed to exert a tonic inhibitory influence on the dopamine (DA)-containing cells of the substantia nigra (SN), and contraversive and ipsiversive circling behaviour can be explained in terms of a greater or lesser activity of the dopaminergic neurones, respectively^{1,2}. However, the blockade of γ -aminobutyric acid (GABA) receptors with intranigral picrotoxin occasionally stimulates rats to turn ipsiversively^{3,4}, rather than evoking the more commonly observed response in the opposite direction⁵. Similarly, injections of GABA agonists into the SN sometimes trigger an atypical contraversive turning syndrome^{3,4,6,7}. We describe here a study which sought to reconcile these paradoxical phenomena by investigating the effects on circling behaviour of decreasing the influence of GABA within the SN with picrotoxin, and of potentiating the action of GABA with *cis*-1,3-aminocyclohexane carboxylic acid (ACHC)⁸, a neuronal GABA uptake inhibitor. We show that the same drugs are capable of producing opposite turning responses when injected into the rostral and caudal parts of the SN. Moreover, behaviour patterns influenced by the anterior SN are accompanied by significant changes in homovanillic acid (HVA) levels in the striatum and require an intact DA system, whereas turning responses initiated by caudal drug injections are apparently not mediated by the dopaminergic nigrostriatal pathway.

Injections of picrotoxin (100 ng) into the rostral SN initiated immediate contraversive rotatory movements and a rise in striatal HVA concentration ipsilaterally, indicating that striatal DA utilisation had risen on the treated side of the brain (Fig. 1*a* and Table 1). By contrast, the administration of ACHC (10 ng) to the same area produced consistent ipsiversive circling and a drop in HVA formation in the corresponding striatum (that is, a fall in DA turnover). Control injections of physiological saline were never observed to alter the animals' behaviour or to modify striatal DA turnover. Groups of 12 rats receiving one or two doses of 6-hydroxydopamine (6-OHDA) showed, one week later, mean falls of 67.5% and 88.4%, respectively, in striatal DA levels. 6-OHDA treatment abolished the turning responses to both rostral picrotoxin and ACHC, and significant attenuation of both drug-induced behaviours was achieved with haloperidol (0.4 mg per kg, intraperitoneally) and electrocoagulation of the crus cerebri (Fig. 1*a*). From these data we conclude that the behavioural

Fig. 1 Turning responses elicited by picrotoxin (open columns) and ACHC (shaded columns) injected into the rostral (*a*) and caudal (*b*) regions of the SN (see legend to Table 1). Results are shown for injections made into untreated control animals (first columns, *n* = 12), for groups of six rats pretreated with one (second columns) or two doses (third columns) of 6-hydroxydopamine unilaterally into the median forebrain bundle (4 μ g in 2 μ l, one week earlier), or haloperidol (0.4 mg per kg, intraperitoneally, 30 min previously) (fourth columns), and for rats with one-week-old unilateral electrolytic lesions of the crus cerebri (fifth columns, *n* = 6). Electrolytic lesions were made by implanting fine concentric bipolar electrodes into the crus cerebri close to the mammillary bodies and passing a direct current of 1 mA for 10 s. **P* < 0.01, ***P* < 0.001 compared to controls (Student's *t*-test).

responses to picrotoxin and ACHC, delivered discretely into the anterior region of the SN, were caused by modifying the levels of endogenously released GABA and thereby altering the activity of the DA cells.

We found it was also possible to make rats rotate by injecting either of these two drugs into the caudal area of the SN. Surprisingly, the direction of turning was now opposite to that evoked by rostral drug placements (Fig. 1*b*). We have no evidence that these caudally evoked responses involved the nigrostriatal DA system, as there were no corresponding changes in striatal HVA production (Table 1) and the behaviours were scarcely attenuated by successful lesions of the median forebrain bundle (Fig. 1*b*). Similarly, haloperidol only slightly reduced ACHC-induced contralateral rotation, whereas picrotoxin-induced ipsilateral movements were completely insensitive to DA receptor blockade. Interestingly, both drugs were more or less equally effective when administered to the caudal SN of crus cerebri-lesioned rats, suggesting to us that the GABA afferents to the anterior and posterior areas of this nucleus may follow separate paths.

The finding that the direction of turning elicited by intranigral injections of picrotoxin and GABA-like drugs depends on whether the compounds are delivered rostrally or caudally in the SN offers a simple explanation for the contrasting behavioural actions of these drugs that have been reported by different investigators^{4,7,12}. The traditional notion of an inhibitory link between GABA- and DA-containing neurones in the rostral SN therefore seems sound, but it does not account for the opposite action of GABA in the caudal SN. Two possible explanations warrant consideration. Where contraversive rotation induced by the intranigral administration of GABA-like drugs¹² can be related to increased nigrostriatal dopaminergic activity¹³, it may be conjectured that the compounds are acting indirectly by suppressing the activity of nigral inhibitory interneurones, thereby de-inhibiting (that is, exciting) the nigrostriatal DA pathway^{13,14}. On the other hand, we have found that behavioural responses elicited by modifications to the GABA system in the caudal SN are resistant to inhibition by procedures which attenuate nigrostriatal DA cell activity. We interpret this to mean that a second

Table 1 Influence of intranigral picrotoxin and ACHC on striatal HVA concentration

Drug treatment	Placement	Striatal HVA concentration (μ g per g wet weight)		<i>P</i>
		Contralateral	Ipsilateral	
Picrotoxin	Rostral	0.35 $\pm$ 0.02	0.69 $\pm$ 0.04	< 0.001
	Caudal	0.38 $\pm$ 0.02	0.36 $\pm$ 0.02	NS
ACHC	Rostral	0.39 $\pm$ 0.02	0.23 $\pm$ 0.02	< 0.001
	Caudal	0.41 $\pm$ 0.02	0.46 $\pm$ 0.02	NS

Male Wistar albino rats (Tuck, 190–210 g) were anaesthetised with halothane and injected stereotactically (0.1 μ l over 5 min) with picrotoxin or ACHC into the rostral (A2.5, L2, D-2) or caudal (A1.6, L2, D-2) regions of the SN⁹. On recovery, rats were placed singly in cages and the numbers of complete revolutions made in a minute were scored every 5 min for a total of 30 min. DA¹⁰ and HVA¹¹ were assayed fluorimetrically in corpora striata dissected from the brains of separate groups of rats injected intranigral with the drugs and killed after 15 min when the frequency of turning was highest. Each value is the mean $\pm$ s.e.m. of six separate experiments. NS, not significant by Student's *t*-test.

system of non-dopaminergic (excitatory?) neurones originates in the region of the SN and cooperates in the control of motor activity and that these, too, are under inhibitory GABA control.

Striatal dopamine release and contraversive rotation elicited by intranigally applied muscimol

SEVERAL lines of evidence indicate that release of dopamine (DA) within the corpus striatum mediates turning behaviour in the rat^{1,2}. The turning occurs in a direction away from the striatum with the greatest activation of DA neurones. Contraversive turning also occurs after unilateral microinjection of agonists of γ -aminobutyric acid (GABA) into the substantia nigra (SN)^{3–6}, the site of origin of the dopaminergic nigrostriatal pathway. This finding was unexpected, as GABA inhibits neurones^{7,8} thought to be DA-containing cells^{9,10} in the SN. Hence, a GABA agonist would be expected to cause a decrease in the rate of release of striatal DA on the microinjected side and result in ipsiversive turning. Therefore, it is unclear whether a GABA agonist applied to the SN alters DA release in the ipsilateral striatum to evoke turning, or whether the turning results from a non-dopaminergic mechanism⁵. The dopamine antagonist, haloperidol, has been reported either to reduce significantly^{3,6} or exert no action on^{4,5} the contraversive turning response evoked by intranigral injection of a GABA-like compound. To clarify the action of GABA on the nigrostriatal dopaminergic system, we examined the effect of muscimol, a potent GABA agonist¹¹, on striatal DA metabolism and release. We report here that intraperitoneally (i.p.) administered muscimol increases the concentration of striatal homovanillic acid (HVA) and that intranigral perfusion of muscimol simultaneously evokes both contraversive turning and DA release from the ipsilateral striatum.

The effect of peripherally administered muscimol on the striatal levels of DA and its major metabolite, HVA, are given in Table 1. The concentration of striatal HVA was increased significantly at 0.5, 1 and 2 h after muscimol (2 mg per kg, i.p.) injection, whereas the concentration of DA was not altered. These results agree with those obtained in mice¹² and suggest that systemically administered muscimol can stimulate turnover or release of DA in the striatum.

Table 1 Effect of muscimol on rat striatal dopamine and homovanillic acid

Time (h) after muscimol	Concentration (nmol per g + s.d.)	
	Dopamine	Homovanillic acid
0	21.5 ± 3.3	1.9 ± 0.5
0.5	21.2 ± 7.8	2.8 ± 0.6*
1.0	24.3 ± 6.3	3.5 ± 1.1*
2.0	22.2 ± 7.9	4.0 ± 1.6*
4.0	20.9 ± 4.9	2.3 ± 0.9

Male Sprague-Dawley rats (Charles River, $n = 6$ per group) were given muscimol (2 mg per kg) intraperitoneally. Zero time control rats were treated with the vehicle (0.9% saline). Dopamine and homovanillic acid were extracted simultaneously from the same tissue sample and measured by a fluorometric method as described previously²⁵.

* Different from vehicle-treated control, $P < 0.02$ (Student's t test).

To evaluate the effect of muscimol on DA neurones further, the striatal release of the neurotransmitter was studied, using a push-pull cannula, while simultaneously perfusing a solution of muscimol through a second push-pull cannula in the ipsilateral SN. For push-pull perfusion, seven male Sprague-Dawley rats weighing 480–550 g, with a guide cannula chronically implanted in the corpus striatum and SN, were used. One week after surgery, a concentric push-pull cannula¹³ was lowered into the striatum and an artificial cerebrospinal fluid (CSF)¹⁴ containing 50 μ Ci ml⁻¹ of ³H-tyrosine (40–50 μ Ci mmol⁻¹) was perfused at a rate of 30 μ l min⁻¹. The experiment, modified from that of Nieoullon *et al.*¹⁵, consisted of eight serial 15-min perfusions of the striatum. During the fifth and sixth striatal perfusion, 10⁻⁴ M muscimol or the CSF vehicle was perfused simultaneously through the SN. A 400- μ l aliquot of each striatal perfusate was assayed for ³H-DA content using the ion-exchange method of Neff *et al.*¹⁶.

Each animal was used in two experiments spaced by a one-week interval. CSF was perfused through the SN in one and muscimol (10⁻⁴ M) in the other. Muscimol was used first in four

Fig. 1 The mean ($\pm$ s.e.m.) ³H-DA efflux detected in eight consecutive push-pull perfusates collected in the striatum. The radioactivity due to ³H-DA is expressed as a % of the spontaneous release value (indicated by the dotted line) as defined in the text. The horizontal bars (▨) indicate the periods during which either muscimol (10⁻⁴ M) (a) or CSF (b) was simultaneously perfused through the SN.

* Significant difference between groups ($n = 5$) using the Mann-Whitney U -test ($P < 0.002$).

Fig. 2 A sagittal section of the rat brain depicting the areas perfused. The stippled section in the dorsal striatum encompasses the sites at which ^3H -tyrosine was perfused and ^3H -DA release was measured ($n=6$). The cross-hatched section in the SN encompasses the area in which muscimol was perfused ($n=7$), whereas the site in the globus pallidus at which no increased ^3H -DA release was noted during the muscimol perfusion is indicated by the black spot.

animals. The mean amount of ^3H -DA in the four perfusates preceding the SN perfusion was used as a value indicative of spontaneous ^3H -DA release (SR). ^3H -DA in each perfusate was expressed as a percentage of the SR and compared between muscimol and CSF perfusions using the Mann-Whitney U -test. The mean SR for 56 perfusates was 3.35 ± 0.62 (s.e.m.) nCi per ml of effluent. Each perfusion site was verified using the atlas of König and Klippel¹⁷.

In five rats, both contraversive turning and a significant efflux of ^3H -DA within the ipsilateral striatum were observed. As shown in Fig. 1, the efflux of ^3H -DA rose significantly during the muscimol perfusion and remained elevated in the subsequent perfusates. ^3H -DA release reached a maximum of 400% of SR in the first striatal effluent collected after stopping muscimol perfusion. The contraversive turning response to muscimol began with latencies varying between 30 s and 8 min, possibly due to slight differences in cannula placement. As with the release of ^3H -DA, contraversive turning and postural asymmetries also persisted after the cessation of the muscimol perfusions. Perhaps the persistent ^3H -DA efflux, circling behaviour, and contralateral postural asymmetries were caused by muscimol which had diffused into surrounding tissue. If as little as 0.01% of the perfused muscimol solution had diffused into the SN, it would be equivalent to a 1-ng microinjection of muscimol, a dose which has been reported to evoke contraversive turning⁵.

Increase of ^3H -DA release occurred only during or following the perfusion of muscimol which concomitantly evoked contralateral turning. Hence, only animals which both turned contraversively in response to muscimol and had verified neo-striatal and nigral perfusion sites were included in the group data. In one animal which did not turn during the muscimol perfusion, there was no increase in ^3H -DA in the striatal perfusate. As shown in Fig. 2, one striatal perfusion site was actually in the globus pallidus. Although this animal turned during the muscimol perfusion, no significant ^3H -DA efflux was observed from the pallidal site.

The SN perfusion of the potent GABA agonist, muscimol, both releases ^3H -DA in the ipsilateral striatum and evokes contraversive turning, supporting the hypothesis that muscimol-evoked turning and striatal DA release are causally related and suggesting that striatal DA mediates the turning. Muscimol may act to release DA neurones from tonic inhibition mediated by other SN neurotransmitters which include: substance P (ref. 18), acetylcholine¹⁹, serotonin¹⁹, dendritic DA²⁰ and glycine²¹. Using the 'encephalé isolé' preparation in the cat, Chéramy *et al.*²²⁻²⁴ have already demonstrated that several of these putative transmitters can modulate striatal ^3H -DA release when they are perfused through the SN. Future studies of the effects of

muscimol on these substances may help to determine the precise mechanism whereby intranigally administered muscimol evokes both contraversive turning and striatal DA release.

Coupled motoneurones are part of the crayfish swimmeret central oscillator

SWIMMERETS in the crayfish are the paired ventral abdominal appendages which beat in a metachronal rhythm during behaviours such as swimming and burrow ventilation. Each swimmeret is driven by alternating bursts of impulses in antagonistic power- and return-stroke motoneurones. Although proprioceptive input affects the detailed structure of the rhythm, the basic motor programme can be elicited from the deafferented abdominal central nervous system (CNS) by tonic stimulation of single 'command fibres' in the ventral nerve cord¹⁻³. Each swimmeret is controlled by a hemiganglion capable of generating the rhythm in isolation, although normally the most posterior swimmeret ganglion (the 5th) acts as a pacemaker, regulating the activity of the other ganglia through a series of coordinating fibres located in the medial region of the ventral nerve cord⁴. I report here the preliminary results of an investigation into the structure of the central neural oscillator controlling swimmeret movements in crayfish. The results suggest that motoneurones in this system do not act merely as output elements which passively relay the activity of an oscillator formed from pre-motor neurones within the CNS, but that the motoneurones themselves are an integral part of the pattern generating circuits. There is both excitatory and inhibitory central coupling between motoneurones mediated either by electrical or graded chemical synapses. Furthermore, the activity of some motoneurones can directly influence the intensity, period, and phase of the oscillation.

Experiments were performed on the 4th abdominal ganglion of *Pacifastacus leniusculus*, which was attached to the rest of the

abdominal CNS, but isolated from the peripheral and rostral nervous system. Intracellular recordings were made with microelectrodes penetrating neuropilar regions of motoneurons from the dorsal surface of the desheathed ganglion. Extracellular pin electrodes were placed on the anterior and posterior branches of the 1st root, for recording and stimulating return-stroke and power-stroke motoneurons respectively. In some of the experiments reported here rhythmic motor output could be elicited by stimulating either the anterior or posterior branch of the 1st root at 25 Hz for 1–2 s. No attempt was made to stimulate command fibres. Occasionally, spontaneous rhythmic output was observed without any prior stimulation. The results of one typical experiment are described in detail below and then a summary is given of conclusions derived from a number of experiments.

A neurone was identified as a power-stroke motoneurone because it had an axon in the posterior branch of the 1st root, but not in the anterior branch (Fig. 1*a, b*). During spontaneous rhythmic output its membrane potential showed subthreshold oscillations, receiving excitatory postsynaptic potentials (e.p.s.ps) late in the burst of spikes recorded from other neurones in the posterior 1st root, and inhibitory post-synaptic potentials (i.p.s.ps) during the burst in the anterior 1st root (Fig. 1*c*). It was thus likely to be a fast excitor power-stroke motoneurone⁵. Injection of subthreshold depolarising current into this neurone when the rhythmic output was not being expressed caused an increase in the tonic spike frequency of other neurones with axons in the posterior 1st root. Conversely, hyperpolarising this neurone caused a decrease in the spontaneous spike frequency of such neurones (Fig. 2*a*). Since these effects result from subthreshold changes in membrane potential in a CNS isolated from the periphery, I conclude that this power-stroke excitor motoneurone is coupled to other power-stroke neurones either through nonrectifying electrical synapses or through graded chemical synapses in which there is a continuous release of excitatory transmitter by the resting neurone which can be increased by depolarisation and decreased by hyperpolarisation⁶.

This motoneurone was also coupled to pre-motor elements. When the motoneurone did not receive rhythmic input, it often received a tonic barrage of apparently unitary e.p.s.ps at ~20 Hz, which was continuous for many minutes with a very stable frequency. The frequency of this barrage was not affected by low levels of injected current (which were sufficient to

Fig. 1 Identification of a fast power-stroke excitor motoneurone. *a*, Triggering the oscilloscope sweep from a spike recorded intracellularly (lower trace, induced by injecting depolarising current) shows a phase-locked spike recorded extracellularly in the posterior (power-stroke) branch of the 1st root (middle trace) but none in the anterior (return-stroke) branch (upper trace). *b*, Stimulating the posterior branch causes an antidromic spike (arrow) which is recorded intracellularly. A spike is also recorded in the anterior branch, but not consistently. *c*, During periods of oscillator activity, the motoneurone (upper trace) receives rhythmic subthreshold depolarisations approximately in phase with bursts of spikes of power-stroke motoneurons in the posterior branch (lower trace) and in antiphase with the weak burst of spikes of return-stroke motoneurons in the anterior branch (middle trace).

Fig. 2 *a*, Hyperpolarising current (middle trace) injected into the motoneurone (lower trace, bridge circuit only approximately balanced) decreases the spontaneous spike frequency of units in the posterior branch (upper line), while depolarising current increases their frequency. *b*, Hyperpolarising the motoneurone partially inhibits an excitatory presynaptic neurone.

demonstrate the motoneurone coupling), but with larger amplitudes of hyperpolarising current, the e.p.s.p. barrage became discontinuous (Fig. 2*b*). When present, the e.p.s.ps still occurred at ~20 Hz, but the previously continuous barrage was now broken by silent periods up to several seconds in duration. The e.p.s.ps were augmented in amplitude by the hyperpolarisation and thus were probably chemical. No spikes recorded in the anterior or posterior 1st root were phase locked to these e.p.s.ps, and so they are unlikely to be the result of reciprocal coupling from another motoneurone. Whatever the origin of these e.p.s.ps, the result demonstrates that this power-stroke excitor motoneurone is coupled to its own pre-motor excitor neurones, which suggests a positive feedback loop within the CNS.

When the CNS was producing the rhythm which in the intact animal causes swimmeret beating, the parameters of the oscillation could be altered by injecting current into this single motoneurone. Hyperpolarising current (~3 nA) caused a reduction in the number of units active during the power-stroke phase of the cycle and an increase in the activity of units in the return-stroke phase of the cycle. There was also a decrease in the frequency of oscillation and a disturbance of the strict reciprocity of power- and return-stroke activity (Fig. 3*a*). This could be seen not only in terms of the motor output as recorded extracellularly in the 1st root, but also as the synaptic input impinging upon the motoneurone. The i.p.s.ps during the return phase disappeared, probably because the membrane potential was near their reversal potential, while the e.p.s.p. barrage of the power-stroke phase became prolonged. These e.p.s.ps were similar in shape and intra-burst frequency to those described above in the quiescent preparation, but their identity remains a matter of speculation. More extreme hyperpolarisations (~5 nA) eliminated the rhythmic motor output altogether. Injection of small depolarising currents (1–2 nA) increased the number of units active in the power-stroke phase (including recruiting spikes in the injected motoneurone itself) and decreased the activity during the return-stroke phase. Hyperpolarising currents had the opposite effect (Fig. 3*b*). The depolarising current had no significant effect on the period of the rhythm, but the hyperpolarising current slowed it by 6% ($P < 0.025$). Continuous injection of larger depolarising currents strongly inhibited return-stroke activity, and increased the activity of a number of power-stroke neurones to the extent that it became difficult to distinguish any rhythmicity in the motor output. However, injection of pulses of such depolarising current had a strong resetting effect on the oscillator, including both the power- and return-stroke phases of the rhythm (Fig. 3*c*).

The levels of current used in these experiments were low (≤ 5 nA), and thus it is likely that the changes in motoneurone membrane potential occurring in the absence of experimental interference are effective in producing the central interactions. Much larger currents (10–20 nA) injected into extracellular space immediately after withdrawing the microelectrode from the neurone had no effect. The preparation remained healthy for several hours, and both the coupling to other motoneurons and the effects on the oscillation of injecting current into the

Fig. 3 *a*, Hyperpolarising current (2nd trace) injected into the motoneurone (upper trace) reduces the intensity of the power-stroke motor activity (bottom trace) and increases the period of the oscillation. There is greater than usual overlap between power- and return-stroke (3rd trace) activity. (The apparent motoneurone hyperpolarisation about 2 s after the start of current injection is caused by a change in the bridge balance.) *b*, Small depolarising currents (i) increase the intensity of power-stroke activity and decrease the intensity of return-stroke activity, while small hyperpolarising currents (ii) have the opposite effect. Note the slight difference in period between (i) and (ii). *c*, Injecting a pulse of depolarising current (bridge unbalanced) can reset the phase of the oscillator. The solid bars under the record indicate the times at which power-stroke activity would have been expected had there been no resetting.

motoneurone could be demonstrated repeatedly and consistently.

The oscillator has been reset by injecting current (<5 nA) into a single neurone in a total of four separate preparations—twice when depolarising current was injected into power-stroke motoneurons, and twice when depolarising current was injected into neurones which did not spike in response to depolarising current (up to 10 nA). Two other power-stroke motoneurons did not reset the oscillator when injected with similar levels of depolarising current. This variability may be due to differences in the sites of current injection relative to central output synapses of the motoneurons. Alternatively it may reflect genuine differences within the population of motoneurons. This latter is quite likely, since the lobster swimmeret motor pool consists of about 50 motoneurons innervating 11 muscles per swimmeret⁵, and the crayfish swimmeret system is probably just as complex. The gross distinction of power- and return-stroke motoneurons used in this work takes no account of basipodite rotators, exopodite openers, closers, benders and so on which cannot yet be identified in the isolated central nervous system. To determine what proportion of the total motor pool has access to the oscillator will require many more experiments.

Penetrations of power- and return-stroke motoneurons in more than 10 preparations which were not oscillating (and whose motoneurons could therefore not be tested for access to the oscillator) has revealed that coupling between motoneurons is widespread. Only rarely have motoneurons been found which did not exhibit some form of coupling. In general, this coupling is organised such that depolarising current

injected into one motoneuron excites its synergists and inhibits its antagonists, while hyperpolarising current has the opposite effect. In at least two pairs of power-stroke motoneurons the coupling is reciprocal and seems to be the result of an electrical synapse. Interactions are strongest between ipsilateral motoneurons within a ganglion, but have also been shown between motoneurons in adjacent ganglia. As yet no coupling has been found between contralateral motoneurons.

These results show that in the neural system controlling swimmeret movements the activity of at least some motoneurons can influence the intensity, frequency, and phasing of the rhythmic motor output from an isolated CNS. This suggests that these motoneurons themselves are part of, or at least can interact with, the oscillator circuit, and are thus not simply passive output elements. Furthermore, since none of the motoneurons from which I have recorded are endogenous pacemakers, the parameters of the oscillator must be a property of a network of neurones. The coupling between motoneurons demonstrated in the quiescent CNS may be a result of direct connections between the motoneurons, or may be mediated by interneurons, perhaps some of the same interneurons as those involved in the oscillator circuit.

Evidence for the functional involvement of carotenoids in the photoperiodic reaction of spider mites

PHOTOPERIODISM in insects and mites depends on the presence of light-absorbing pigments, which are probably located in the central nervous system; photoperiodic responses are mediated by the direct action of light on these nervous elements¹. Until now, pigments involved in photoperiodic processes such as diapause and polymorphism have not been identified. Different groups of pigments have been named by various authors as possible candidates for this function. A biologically active role based mainly on action spectra studies and the absorption characteristics of isolated pigments has been suggested for pterins², carotenoids³, a combination of carotenoproteins, flavoproteins and haemoproteins⁴ and bile pigments⁵. Carotenoids, pterins and flavins have also been proposed as possible photoreceptor pigments in studies on the spectral sensitivity of circadian rhythms⁶. According to Lees¹, however, the usefulness of action spectra in identifying the light acceptor is limited, as spectra for photoperiodic action cannot at present be matched against absorption curves. A different approach was used by Zimmerman and Goldsmith⁷, who reared *Drosophila* on a carotenoid-free diet and showed that in one generation the sensitivity of the visual receptors was lowered by 3 log units because of lack of rhodopsin. At the same time the photosensitivity of the rhythm of pupal eclosion in the cultures was not affected, from which it was concluded that the pigment involved in mediating light effects on the circadian rhythm in *Drosophila* is not a carotenoid derivative. We demonstrate here that carotenoids are functionally involved in the photoperiodic induction of diapause in the spider mite *Tetranychus urticae* using a method involving pigment mutants.

In *T. urticae*, only adult females may undergo a facultative diapause, induced by short-day photoperiods experienced during the larval and nymphal stages. With the test regime used (10L:14D, 18 °C) the different wild-type strains showed a 100% diapause⁸. From a wild-type strain we have isolated seven different pigment mutants, all due to single recessive mutations which interfere with the uptake and oxidative metabolism of β -carotene in these mites⁹. It seemed that only the albino mutant showed a lowered diapause response, all other pigment mutants exhibiting 100% diapause in the above test regime. Four albino mutants, which arose spontaneously in different wild-type strains, all responded with a lowered diapause, although all four originated from wild-type strains which give 100% diapause in the test conditions. Complete diapause has never been observed in any albino strain; although highly variable in expression (diapause responses range over 0–80% in different tests), the percentage diapause in albino strains is always markedly reduced in comparison with wild type. Back-crossing of three of the albino mutants to wild type for 10 generations did not restore the capability to diapause. As crossing-over is thought to occur very frequently in these mites¹⁰, these findings are a strong indication for a functional involvement of the albino locus in the photoperiodic reaction of *T. urticae*.

Even stronger evidence for a functional connection between the presence of carotenoid pigments and diapause was obtained in other crossing experiments between wild type and albino. For these crosses use was made of the male haploidy (arrhenotoky)

in *T. urticae*. The out-cross of the albino mutant to wild type gives hybrid daughters which are phenotypically wild type and diapause normally. Crossing these hybrid females to albino males produces a mixed female offspring, consisting of wild type and albino in a 1:1 ratio. Surprisingly, both these categories show a 100% diapause when tested in the photoperiodic regime mentioned above. Albino females of this offspring, after random mating with their brothers, which also consisted of a 1:1 ratio of wild type and albino, again gave rise to a mixed offspring of wild-type (hybrid) and albino females. From these, the wild-type females all diapaused on short-day treatment, whereas the albino daughters showed the same lowered diapause response as described for the different albino strains. From these crosses it seems that 100% diapause in albino is realised only when the albino daughters come from hybrid, phenotypically wild-type mothers. Apparently a maternal effect is responsible for the complete induction of diapause in albino females.

The lowered diapause response encountered in all albino strains and the fact that the capability to diapause could not be restored by a series of back-crosses to wild type, suggest that the albino locus exerts a pleiotropic effect, influencing both pigmentation and diapause induction. The discovery of the maternal effect in the crossing experiments described above confirms this supposition and leads us to conclude that carotenoids are functionally involved in diapause induction in *T. urticae*. With respect to pigmentation, a maternal effect, consisting of small red eyespots in albino males produced by wild-type hybrid females, has been demonstrated previously in these mites¹¹. This showed that the egg of spider mites transmits a certain amount of carotenoids, which may be used for the formation of eyespots. From the experiments described above it could be concluded that these maternally derived carotenoids may also be utilised by the embryo in the formation of a photopigment concerned in the induction of diapause. Very small amounts of pigment would probably suffice for this function. A more elaborate account of these and other results will be published elsewhere.

Evidence for passive electrotonic interactions in red rods of toad retina

SINCE Baylor, Fuortes and O'Bryan¹ first demonstrated interactions between vertebrate photoreceptor cells, many types of inter-receptor influences have been described^{2–10}. While some of these interactions are mediated by horizontal cells^{1,2,6}, others apparently result from direct contact between the photoreceptors themselves^{1,3,4,7–10}. Fain *et al.*¹⁰ reported that the red rods of the toad *Bufo marinus* were coupled by gap (electronic) junctions, and that single rods received detectable signals from other receptors over a retinal area of about 0.5 mm². This

receptive field area is 4–100 times larger than those measured for photoreceptors of a variety of species^{1,4,7,9,11,12,15}. Fain *et al.* found this extensive spread of rod signals to be inconsistent with network models containing only passive elements and this raised the possibility that some active process, perhaps in the rod membrane, contributed to the spread of rod signals. We report here results which indicate that single rods sum signals over only 1/16th the area previously estimated; this smaller receptive field area implies more intrinsic noise, a larger response to single photon absorptions, and a larger signal-to-noise ratio than predicted by the previously reported results¹⁰. Furthermore we find that, as in other species (ref. 13, and Copenhagen and Owen, personal communication), the spread of low-amplitude, light-evoked responses between photoreceptors can be accounted for by purely passive electrical properties.

Bufo marinus red rods were impaled in eye cup preparations and identified by their characteristic slow waveforms^{3,14,15}, spectral sensitivities^{14–17}, and by injection of Procion yellow. Receptive field properties were determined using two different stimulus configurations.

Two of us (H.F.L. and D.R.C.) recorded rod responses to a long, narrow bar of light flashed at various regions of each rod's receptive field. This bar was moved across the retina in a stepwise fashion, perpendicular to the long axis of the stimulus, and at positions separated by either 9.0 or 13.5 μm the stimulus was flashed from three to six times. Multiple responses, recorded to flashes at each position, were computer averaged and the peak amplitudes plotted semi-logarithmically as a function of slit displacement (Fig. 1). For all cells tested, the light response decreased exponentially as the bar was moved from the centre to the periphery of the receptive field. Such behaviour is predicted by two-dimensional cable models and permits the spatial properties of the response to be characterised by a length constant λ (refs 18, 19). For 11 rods tested, the mean length constant was $24 \pm 5 \mu\text{m}$ ($\pm$ s.d.) (Table 1).

In independent experiments, receptive field properties of toad rods were measured by one of us (R.A.N.) using flashed circular spots of light of increasing diameter. A small, dim spot of light (13–30 μm diameter) was centred over the most sensitive region of the rod's receptive field, and photoreponses were recorded as the diameter of the spot was increased from 13 to 265 μm at a constant, dim light intensity (Fig. 2, inset). For the cell shown in Fig. 2, the response to these flashes increased asymptotically to a diameter exceeding 200 μm . The diameter of the summation area (95% V_{FF}) was taken as 160 μm . The continuous curve represents the relationship between spot diameter and central voltage response for a continuous two-dimensional resistive sheet with a length constant of 18 μm . This relationship is described by

$$V(d) = V_{\text{FF}} \left\{ 1 - \left[\frac{d}{2\lambda} K_1 \left(\frac{d}{2\lambda} \right) \right] \right\}$$

where $V(d)$ is the voltage at the centre of the illuminated circle of diameter d , V_{FF} is the voltage with full field illumination, and K_1 is a modified Bessel function^{18,19}. For 14 rods tested in this manner, the mean length constant was $21 \pm 6 \mu\text{m}$ ($\pm$ s.d.).

These results indicate that red rods are functionally coupled over an area of approximately 0.03 mm^2 rather than 0.5 mm^2 as previously estimated¹⁰. Thus, each rod is functionally coupled to a maximum of 500–550 other rods rather than to 8,000–9,000 (refs 10, 20). We have also learned that two other investigators (ref. 21, and G. Gold, personal communication), recording from red rods in isolated *Bufo* retinal preparations (rather than in eye cups), have found summation areas comparable to those reported here.

This smaller receptive field size has several implications for the physiology of *Bufo* red rods. For example, the magnitude (r.m.s. value) of the intrinsic noise (membrane events not caused by the absorption of a photon) in a coupled rod should be inversely related to the diameter of the summation area (proportional to λ); this assumes that coupling serves to average

Fig. 1 Response of a *Bufo marinus* red rod as a function of the displacement of a narrow stimulus bar. The bar was moved through the receptive field of each cell twice. $\circ$, Data collected during the first pass of the bar; $\bullet$, data collected as the bar was moved in the opposite direction. Points are the computer average of three to six responses at each position. Solid lines were fitted by the method of least-squares error. The bar was produced by passing the light beam through a rectangular slit formed by two razor blades. The image of the slit on the retina had a nominal halfband width of 8 μm as determined by passing the image across a 5- μm entrance aperture to a photomultiplier tube which was in the position normally occupied by the eye cup. The length of the bar was limited by an iris diaphragm and was 750 μm in the central position. Responses were elicited by 40-ms flashes of 514 nm light delivering to the retina about 120 photons per μm^2 per flash. Details of the optical system and its calibration are described elsewhere⁷.

noise sources across many rods as it does with turtle cones¹³. Thus, the smaller summation area would increase estimates of intrinsic noise by a factor of ~ 4 . Similarly, estimates of the coupling resistance between *Bufo* red rods would be larger for this smaller summation area, and one would expect less shunting of signals to adjacent rods. Quantitatively, estimates of input resistance, and hence the signal generated by the absorption of a single photon, would be increased by a factor of ~ 10 . Therefore,

Table 1 Summary of length constants for 11 *Bufo marinus* red rods

Rod no.	λ_-	r_-^2	λ_+	r_+^2	V_{centre} (mV)
1	25.9	0.99	24.6	0.97	2.2
2	26.1	0.96	24.6	0.97	3.4
3	33.8	0.99	18.9	0.98	2.7
4	24.2	0.98	23.2	0.98	2.2
5	22.3	0.94	17.8	0.98	2.0
6	24.0	0.99	25.4	0.97	2.4
7	21.7	0.98	24.7	0.96	1.0
8	31.3	0.99	28.8	0.95	2.3
9	26.3	0.99	21.7	0.99	2.7
10	28.3	0.99	25.0	0.97	2.2
11	15.5	0.99	12.6	0.99	1.8

λ_- and λ_+ represent length constants on opposite sides of the centre for individual rods; r_-^2 and r_+^2 are the coefficients of correlation between the data and a simple exponential function (Fig. 1). V_{centre} is the amplitude of the light response when the stimulus bar was over the central (most sensitive) part of the field. Differences between λ_- and λ_+ could not be attributed to retinal position or optical factors. Similar asymmetries have been seen in other species (ref. 18, and Copenhagen and Owen personal communication). The mean of these 22 length constants is $23.9 \pm 4.7 \mu\text{m}$ ($\pm$ s.d.).

Fig. 2 Amplitude of photoresponses (circles) to 500-ms flashes of a dim circular spot of white light as its diameter was increased from 13 to 265 μm . The solid curve is the relationship between spot diameter and response amplitude for a continuous two-dimensional sheet which exhibits a length constant of 18 μm . Inset: photoresponses recorded (from top to bottom, respectively) at 13, 23, 47, 82, 131, 167, 219 and 265 μm spot diameters (curves displaced for illustration). Spots were generated with either an iris diaphragm (for the large spots) or with a plate containing a variety of apertures (for small spots). Spot diameters were calibrated by observing the image cast on the retina with a microscope containing an ocular reticle. Details of the optical system and its calibration are described elsewhere¹⁵.

the predicted signal-to-noise ratio for single photon capture would be increased by a factor of ~ 2.5 . Most importantly, our data show that the spatial properties of *Bufo* red rod responses are well described by an exponential for thin bar-shaped stimuli and a modified Bessel function for circular stimuli. Therefore, our results indicate that a network containing purely passive membrane and coupling resistances can account for the extent of spread of signals between *Bufo* red rods.

This research was supported by the National Eye Institute and the National Institute of Neurological and Communicative Disorders and Stroke, USPHS.

Note added in proof: Detwiler *et al.*²² recently reported that the network of turtle rods possesses some properties of a high-pass filter. In the analysis of our data we have assumed a purely resistive network in modelling the spread of *Bufo* rod signals. It can be shown, however, that under the passive network assumptions used by Detwiler *et al.* (their Fig. 1b), the d.c. space constant is still described solely by the resistive network elements if determined from measurements of the peak response amplitude (where $dv/dt = 0$).

Increase in free Ca^{2+} in muscle after exposure to CO_2

IT IS now established that a change in intracellular free Ca^{2+} forms a vital link in the action of certain hormones and neurotransmitters as well as in excitation–secretion and excitation–contraction coupling^{1–5}. Here we report an increase in intracellular free Ca^{2+} (Ca_i^{2+}), brought about by exposure of muscle fibres to CO_2 . This effect may provide an important clue to the mode of action of CO_2 in muscle cells as well as to a possible regulation of Ca_i^{2+} by changes in intracellular pH (pH_i).

Single muscle fibres from the barnacle *Balanus nubilus* were axially injected with the calcium-sensitive photoprotein aequorin⁶, prepared by chromatography from extracts of *Aequorea forskalea*⁴. Usually a period of 2 h was allowed for uniform distribution of the photoprotein internally, after which the light was recorded with an EMI photomultiplier tube (9634A), run at -900 V, with the output (time constant 10 ms) displayed on a pen recorder. The fibres were bathed in artificial seawater (ASW), composition (mM) NaCl 510, KCl 12.9, CaCl_2 11.8, MgCl_2 23.6, NaHCO_3 2.6 and TES 2.0 at pH 7.1 and temperature 17 – 23°C .

If the ASW was replaced with ASW which had been equilibrated with either 5, 10 or 100% CO_2 so that the values of the saline pH were 6.4, 6.1 and 5.0 respectively, the aequorin light emission increased over a period of 10–20 min, reaching in 100% CO_2 a new steady level which was 5–25 times (nine fibres) the initial resting value (Fig. 1b–d). This response to CO_2 was observed immediately after aequorin injection, although the rate at which the steady level was achieved was slower than after the equilibration period of 2 h. If the pH of 100% CO_2 –ASW was adjusted to 6.9 by addition of 100 mM NaHCO_3 (replacing NaCl) there was still a marked increase in aequorin light emission. Application of an ASW at pH 5.0 (buffered with 10 mM NaH_2PO_4 or 10 mM Tris-maleate) produced relatively little change (Fig. 1a) in light emission over 20 min (in some fibres a small increase and in others a decrease in light was observed, the maximum change being 0.3 times the resting light). These last two observations suggested that it was either a direct action of CO_2 or a change in pH_i that initiated the aequorin light response.

The fact that CO_2 does readily change pH_i in these and other cells is well documented^{7–10}. Application of 100% CO_2 –ASW produces a change in pH_i of about 1 unit from 7.2 to 6.2 in crustacean muscle fibres after a period of 10–15 min^{7,8}, whereas phosphate–ASW (pH 5.0) produces a change in pH_i of only about 0.2 pH units over the same period⁷. We have also determined that the increase in light emission seen in CO_2 –ASW was not brought about simply by a direct action of either H^+ or CO_2 on the apparent affinity of aequorin for Ca^{2+} . First, in a synthetic internal solution having the following composition (mM) KCl 150, NaCl 20 and MgCl_2 5, with added Ca^{2+} about 60×10^{-6} , at pH 7.1 with K_2CO_3 (Johnson Matthey) there was no increase in the aequorin light emission after equilibration with 100% CO_2 (pH 5.0 finally) and the records in fact indicate a small inhibitory effect which would be expected from the known values of the apparent binding constants of these ions to the photoprotein at

these different pH values¹¹ (Fig. 1e–g). *In vivo*, the pH_i change would be less than occurred in this assay (see above). Second, the increase in light emission was also accompanied by an increase in isometric tension development (Fig. 1h), which was equivalent to about 0.6% of the maximum tension, P_0 , for this preparation (49 N cm⁻²)¹⁴.

All these experimental observations strongly suggest that the increase in aequorin light emission in CO₂-ASW does in fact represent an increase in free Ca²⁺. Assuming that the free Ca²⁺ is proportional to (aequorin light)^{0.4} (ref. 11), and that the change in Ca²⁺ is uniform within the fibre at the peak of the response, the increase in free Ca²⁺ by 100% CO₂ is calculated to be approximately two to four times, increasing from 70–100 nM (refs 12 and 13) to 140–400 nM, respectively.

It was important to determine whether this increase in free Ca²⁺ resulted from either a stimulation of calcium influx across the surface membrane or a release from internal stores or a combination of both processes. Replacement of ASW with OCa-ASW (Na replaced) reduced the aequorin light response in 100% CO₂ to 7–27% ($n = 6$) of the control response in 100% CO₂-ASW, after 12–50 min in OCa-ASW (Fig. 2) and the

Fig. 1 a–d, Effects of extracellular pH and CO₂ on aequorin light emission from a single muscle fibre in ASW at pH 7.1 TES (*N*-Tris(hydroxymethyl)methyl-2-aminoethanesulphonic acid) a, ASW at pH 5.1 (10 mM Na₂HPO₄), b, c and d, ASW equilibrated with 5, 10 and 100% CO₂ at final pH 6.4, 6.1 and 5.0, respectively. tension response was also abolished. This result seemed to support the idea that a stimulation of Ca²⁺ influx was involved in the response to CO₂. However, measurement of the resting ⁴⁵Ca²⁺ influx across the muscle membrane using the intracellular scintillator probe^{14,15} showed that the unidirectional Ca²⁺ influx was reduced in 100% CO₂-ASW by 40% over a 20-min period (three fibres) (Fig. 3a), whereas in phosphate-ASW (pH 5.0) there was no effect over a similar time (three fibres). These fibres had first been injected with 1 M K₂EGTA solution giving a final intracellular concentration of 11–18 mM per kg in order for the probe to assess accurately the intracellular ⁴⁵Ca²⁺ concentration.

The Ca²⁺ efflux, measured after axial injection of ⁴⁵Ca²⁺ (ref. 16), indicated that in 100% CO₂-ASW there was an average reduction of 53% (three fibres) (Fig. 3b), and in phosphate-ASW (pH 5.0) there was an average reduction of 36% (three fibres) in the rate of Ca²⁺ loss from the cell. Thus, if the Ca²⁺ influx and the Ca²⁺ efflux are approximately equal, then the effects of 100% CO₂ would be to produce a net Ca²⁺ influx equivalent to 13% (about 0.1 pmol cm⁻² s⁻¹) of the resting unidirectional influx. The failure of ASW-phosphate (pH 5.0), which would produce a larger net influx equivalent to 36% of the resting unidirectional influx, to increase the free Ca²⁺ in a similar way to the effect of CO₂-ASW argues against the smaller net influx of Ca²⁺ observed in CO₂-ASW being by itself responsible for the increase in free Ca²⁺. Also, external La³⁺ (2 mM), known to inhibit both the resting Ca²⁺ influx and efflux^{14,17,21} as well as the increase in free Ca²⁺ which occurs in Na-free ASW in these fibres¹⁷, failed to affect significantly the CO₂-induced increase in free Ca²⁺ (the mean response to CO₂ in the presence of La³⁺ was 93% of the control response in ASW ($n = 3$)).

It seemed possible that changes in membrane potential, which have been reported to occur in muscle fibres exposed to CO₂-ASW^{8,18} could have been releasing Ca²⁺ from internal Ca²⁺ stores within the sarcoplasmic reticulum (SR). Measurements with an axial, intracellular electrode (100 μ m tip) filled with KCl (3 M) showed that 100% CO₂-ASW produced a slow depolarisation of 10–15 mV over 20 min (seven fibres). Depolarisations of similar amplitude and duration, produced in the same fibres by 60 K⁺-ASW, resulted in either transient increases in light emission which were less than 10% of the increases observed with 100% CO₂-ASW, or no increases at all.

In conclusion, it seems that external CO₂ application results in an increase in free Ca²⁺ in these muscle fibres and that this cannot readily be attributed to either a net Ca²⁺ influx alone or to a depolarisation of the surface membrane, although a CO₂-induced depolarisation may contribute up to 10% of the observed increase in aequorin light emission. The requirement of the response to CO₂ for extracellular Ca²⁺, as shown by the effects of Ca²⁺-free saline, means that the small net Ca²⁺ influx induced by CO₂-ASW should not be ruled out entirely as a possible cause of the response. If, for example, the CO₂-induced reduction in pH_i also impairs the functioning of the Ca²⁺-ATPase pump in the membrane of the SR, then a small net influx of Ca might lead to an increase in free Ca²⁺. There is evidence from frog skinned muscle fibres that the Ca²⁺ loading of the SR at physiological free Ca²⁺ levels is decreased by a reduction of pH from 7.0 to 6.2 (ref. 19).

Fig. 3 *a*, Effect of CO_2 on $^{45}\text{Ca}^{2+}$ influx, measured in a single muscle fibre using an intracellular scintillator probe. $^{45}\text{Ca}^{2+}$ concentration in muscle fibre (as percentage extracellular $^{45}\text{Ca}^{2+}$ concentration) is plotted against time of immersion in $^{45}\text{Ca}^{2+}$ saline (0.1 mCi ml^{-1}): ASW ($\text{pH } 7.1$), 100% CO_2 -ASW ($\text{pH } 5.0$). Values of the influx ($\text{pmol cm}^{-2} \text{s}^{-1}$), calculated from the slope of the line drawn by linear regression analysis, are shown. Initial fast phase represents filling of extracellular 'cleft' system^{14,15}. Intracellular EGTA 14 mM per kg, $E_m = -47 \text{ mV}$; diameter $1.240 \mu\text{m}$. *b*, Effect of CO_2 on residual $^{45}\text{Ca}^{2+}$ efflux from single muscle fibre which had been axially injected with $^{45}\text{CaCl}_2 + \text{TES}$ ($\text{pH } 7.1$). $^{45}\text{Ca}^{2+}$ appearing in external ASW was counted by liquid scintillation¹⁶. Fractional loss of $^{45}\text{Ca}^{2+}$ ($\text{min}^{-1} \times 10^4$) plotted against time after injection. The pH of 100% CO_2 -ASW was 5.0. $E_m = -48 \text{ mV}$.

A second possible mechanism for the CO_2 response is a stimulation by the reduction in pH_i of a Ca^{2+} -dependent release of Ca^{2+} from the SR, similar to the type which has been proposed to occur in the normal E-C coupling in skeletal muscle fibres²⁰. Relevant to this is the finding that exposure of barnacle muscle fibres to OCa-ASW results in a complete loss of the electrically evoked calcium transient and tension response within 10–15 min (C. C. A. and R. Burles, unpublished). This is thought to reflect a requirement of the E-C coupling process itself for extracellular Ca^{2+} , as the caffeine-releasable internal stores of Ca^{2+} are still reasonably intact at this time²¹ and the amplitude of the extra Ca^{2+} influx which occurs during electrical stimulation in normal saline is insufficient to account for the observed tension development^{14,15}, even if one assumes that all the extra Ca^{2+} binds directly to the contractile proteins.

A third possibility is that there is displacement of Ca^{2+} by H^+ either from some organelle other than the SR or from Ca^{2+} -binding proteins in the sarcoplasm. In this case the effect of OCa-ASW on the CO_2 response could be explained by a ready depletion of this labile intracellular Ca^{2+} store, following the

rapid decline in free Ca_i^{2+} seen in these circumstances (see Fig. 2).

Evidence demonstrating that it may be a reduction in pH_i and not the increase in intracellular CO_2 concentration which is the stimulus for the increase in free Ca_i^{2+} was obtained by injecting muscle fibres with various buffer solutions (1 M $\text{KH}_2\text{PO}_4/0.05 \text{ M Na}_2\text{HPO}_4$, 1 M HEPES or 1 M Tris-maleate). Solutions of $\text{pH } 5.0$ – 5.5 transiently increased the aequorin light emission by up to 10 times, whereas solutions at $\text{pH } 7.2$ did not.

Interestingly, aequorin light emission from squid giant axons is reduced by 5% CO_2 -ASW, and this has been attributed solely to changes in Ca^{2+} fluxes across the axon membrane^{22,23}. The opposite effect of this level of CO_2 on barnacle muscle may mean that in muscle, Ca^{2+} is being released from an intracellular source which is absent in nerve.

Requirements for therapeutic inhibition of sickle haemoglobin gelation

KINETIC studies on haemoglobin S gelation have shown that following initiation of the reaction there is a pronounced delay before the appearance of the polymer^{1–5}. The delay time is extremely sensitive to physiological variables, such as total haemoglobin concentration and fractional saturation with ligand, and moderately sensitive to pH , salt concentration and temperature (near 37°C)^{1,5–10}. Changes in these variables which decrease the delay time seem to be associated with increased clinical severity of sickle cell disease^{1,11}. These findings have been explained by a pathophysiological mechanism in which a decrease in the delay time of intracellular gelation, relative to the capillary transit time, increases the probability of intracapillary sickling; blockage of the microcirculation is then possible, with consequent tissue anoxia and organ damage. An increase in the delay time, permitting cells to escape the narrow capillaries before gelation has begun, is therefore predicted to result in amelioration of the disease^{1,11}. We present here results of kinetic experiments designed to help answer the question: how much must the delay time be increased to obtain a given therapeutic effect in patients?

The gelation kinetics of haemoglobin S were investigated in mixtures with normal adult haemoglobin (A) or fetal haemoglobin (F). Increased proportions of these normal haemoglobins, if homogeneously distributed in the red cell population, are known to be associated with decreased clinical severity¹²⁻¹⁶. By correlating the delay time data on specific haemoglobin mixtures with the data on the associated clinical course, we obtained a quantitative estimate of the increase in the *in vitro* delay time required to produce a particular clinical status. These results, together with other kinetic data, were then used to evaluate various therapeutic strategies.

The kinetic results reported here were derived from temperature-jump experiments in which the initiation of gelation was instantaneous relative to the delay time⁷. If initiation is not instantaneous, the observed delay will always be longer, this effect increasing with decreasing delay time. In such conditions, the increases in delay time will be smaller than those reported here. Zarkowsky and Hochmuth⁹, for example, found an increase of only 35-fold for the delay time of morphological sickling of A/S (heterozygous) trait cells relative to S/S (homozygous) cells. Kinetic studies on sickle cells by Rampling and Sirs²⁵ suggest that deoxygenation was not sufficiently rapid to resolve the delay time for S/S cells in the Zarkowsky and Hochmuth experiments. We point out, however, that deoxygenation *in vivo* may also not be fast relative to the delay time, so that experiments designed to mimic this situation will show a decreased sensitivity of the delay time to solution variables.

Figure 1 shows the delay time for the thermally induced gelation of mixtures. The effect of deoxyhaemoglobin F on the delay time is considerably larger than the effect of deoxyhaemoglobin A. This result is expected from previous equilibrium and minimum gelling concentration data, which showed that deoxyhaemoglobin F has a larger inhibitory effect than deoxyhaemoglobin A^{6,7,21-24}. A detailed experimental and theoretical analysis of both the kinetic and equilibrium data will be presented elsewhere²⁰.

In the double heterozygous conditions of sickle/ β^+ -thalassaemia, red cells contain about 15–30% haemoglobin A¹². In mixtures of these compositions we measured a 10–100-fold increase in delay time. Although, as in homozygous sickle cell disease, the clinical severity is quite variable, S/ β^+ -thalassaemia is in general less severe than S/S disease^{12,13}. Our kinetic results suggest, then, that some therapeutic effect might result if the delay time of gelation were increased by a factor of 10–100. In the double heterozygous condition of sickle/hereditary persistence of fetal haemoglobin (S/HPFH), red cells contain about 20–30% haemoglobin F^{12,14}. Such mixtures increase the delay time 10^3 – 10^4 -fold. Since this condition produces a much milder clinical course than S/S disease^{12,14}, increasing the delay time by a factor of 10^3 – 10^4 can reasonably be expected to have a major therapeutic effect in patients. Finally, in sickle cell trait, red cells contain ~60% haemoglobin A and 40% haemoglobin S^{13,15}. The increase in delay time found for a mixture of this composition is ~ 10^6 -fold. Patients with sickle cell trait rarely show any clinical manifestations¹⁶. Increasing the delay time, then, by about a factor of 10^6 , could be expected to produce a 'cure' of S/S disease.

Three different strategies to increase the delay time of intracellular gelation have been suggested. One is to directly inhibit polymerisation with molecules that competitively bind to sites of intermolecular contact. A second is to inhibit polymerisation indirectly by increasing the haemoglobin oxygen affinity, thereby increasing the fractional saturation in capillaries. A third strategy, suggested by previous kinetic studies, is to decrease the intracellular haemoglobin concentration^{1,11}.

We can estimate the requirements for each strategy. The decrease in intracellular haemoglobin concentration, Δc , required to produce a given increase in the delay time, t_d , can be directly calculated from the measured concentration dependence: $d \log t_d / d \log c = -(35-55)$ (refs 1, 6, 20). In the limiting case where a molecule binds to a single site and completely prevents incorporation into the polymer, the frac-

Fig. 1. Effect of deoxyhaemoglobin A and F on the delay time of thermally induced gelation. The relative delay time is defined as the ratio of the delay time for the mixture, t_d , to the delay time for deoxyhaemoglobin S alone, $t_d(S/S)$, at the same total haemoglobin concentration. To obtain relative delay times over seven decades at the same total haemoglobin concentration and temperature (286 g l^{-1} and 23.4°C for S-F mixtures, 270 g l^{-1} and 23.0°C for S-A mixtures), delay times were measured as a function of total haemoglobin concentration and temperature using a turbidity technique⁷ and then extrapolated to the same values. All mixtures were initially prepared in the oxy form to permit complete hybridisation¹⁷⁻¹⁹. The curve through the S-F mixture points is theoretical, and is obtained from the equation $\log(t_d/t_d(S/S)) = -s \log(1 - X_F)^2$, which assumes that the molecular species— $\alpha_2\beta_2^S$, $\alpha_2\gamma_2$ and $\alpha_2\gamma\beta^S$ hybrid—are present in a binomial distribution¹⁷⁻¹⁹, and that only the $\alpha_2\beta_2^S$ species polymerises. A least-squares fit to the data gives $s = 13.5$. Details of the experimental procedures and data analysis will be presented elsewhere²⁰.

tional saturation of the site with inhibitor, x , can be calculated from the relation: $d \log t_d / d \log(1 - x) \approx -10$. This derivative is an average of values obtained from experiments in solutions partially saturated with carbon monoxide and from the S-F mixture data in Fig. 1^{20,26}. It is smaller than the corresponding derivative for the concentration dependence because the inhibited molecule, while incapable of being incorporated into the polymer, still occupies space in the solution and thereby increases the kinetically effective concentration of the uninhibited, polymerising molecules^{20,26-29}. Oxygen affinity calculations are more speculative, as the only relevant kinetic result is $d \log t_d / dy \approx 10$ ($0 < y < 0.5$), where y is the fractional saturation of haemoglobin S with carbon monoxide^{7,8}. Assuming that the perturbation responsible for the change in oxygen affinity alters neither the degree of cooperativity nor the delay time for the completely deoxygenated molecule, we can use the result for carbon monoxide to calculate the minimum decrease in p_{50} required to produce a given increase in delay time. Table 1 summarises the results of the above calculations. As solubility is a frequently used assay for gelation, and is related to the delay time by $d \log t_d / d \log c_s = 30-40$ (refs 7, 26, 30), the increase in solubility corresponding to the delay time increase is also shown.

Table 1 suggests that the values of x , Δc and Δp_{50} required to produce a 'cure' of S/S disease are large and will be difficult to achieve. To obtain 75% saturation of a perfect inhibitory site, and simultaneously maintain a low free inhibitor concentration to minimise toxicity, a molecule with a high binding constant is required. A decrease in intracellular haemoglobin concentration of $75-110 \text{ g l}^{-1}$ might be accomplished with a reducti-

Table 1 Clinical course, gelation delay time and requirements for methods of inhibition

Condition	Clinical course relative to S/S disease	Red cell composition			t_d	$\frac{c_s}{c_s^0}$	x	Δc (gl^{-1})	Δp_{50} (mm Hg)
		X_S	X_A	X_F	$t_d(\text{S/S})$	$\frac{c_s}{c_s^0}$			
S/ β^+ -thal.	Less severe	0.85–0.7	0.15–0.3	0	10^{-10^2}	1.06–1.17	0.20–0.37	15–40	>4–7
S/HPFH	Much less severe	0.8–0.7	0	0.2–0.3	10^3-10^4	1.19–1.26	0.50–0.60	40–80	>10–13
A/S trait	No disease	0.4	0.6	0	10^6	1.4–1.6	0.75	75–110	>17

X_i values ($i = \text{Hb S, Hb A, Hb F}$) are mol fractions; $t_d/t_d(\text{S/S})$ is the ratio of the mixture delay time for each composition to the delay time for pure deoxyhaemoglobin S at the same total haemoglobin concentration and is obtained from the data in Fig. 1; c_s/c_s^0 is the ratio of deoxyhaemoglobin S solubility in the presence of inhibitor to deoxyhaemoglobin S solubility without inhibitor; x is the fractional saturation of the inhibitory site required to produce the delay time increase; Δc is the required decrease in intracellular haemoglobin concentration, assuming a mean intracellular concentration of 340 g l^{-1} in S/S disease; Δp_{50} is the required decrease in partial oxygen pressure at 50% saturation with oxygen. For a given increase in the delay time the minimum Δp_{50} can be calculated from the experimental result on solutions partially saturated with carbon monoxide that $d \log t_d/dy \approx 10^{7.8}$, and from the Hill equation, $\log(y/1-y) = n \log(p/p_{50})$. It is assumed that $n = 2.6$ and $p_{50} = 26 \text{ mm Hg}$ for haemoglobin S during the delay period, where a negligible amount of polymerisation has occurred.

in haemoglobin synthesis, by, for example, introducing an iron deficiency (the ideal result would be a ‘switch’ from sickle cell disease to a much less severe anaemia)^{11,31}. An equivalent increase in cell volume (22–32%) would be preferable, as it would presumably result in less interference with oxygen delivery. Increasing oxygen affinity is the most difficult strategy to evaluate. A realistic calculation would require detailed considerations of the kinetics of intracapillary deoxygenation. There is, moreover, insufficient data to evaluate the influence of homeostatic responses that maintain oxygen delivery. A decrease in tissue p_{O_2} to increase oxygen extraction, would, for example, partially buffer the inhibitory effect of an increase in oxygen affinity³². Note, however, that complete suppression of 2,3-diphosphoglycerate synthesis could lower the p_{50} by as much as 10 mm Hg^{33,34}. Finally, we emphasise that the calculations in Table 1 consider only changes in single variables. Both molecular and physiological responses to a particular perturbation could result in simultaneous changes in all three. However, the comparisons in Table 1 suggest that therapeutically significant kinetic inhibition of intracellular gelation could be accomplished by any one of the three approaches.

Many gelation inhibitors have been proposed as specific drugs for sickle cell disease³⁵. The results in Table 1 should provide a useful framework for assessing the therapeutic potential of these inhibitors, particularly in analysing the problem of gelation inhibition versus toxicity. Because very large doses of any single drug would be necessary to obtain a therapeutic effect in patients, it will probably be necessary to employ several drugs simultaneously, taking advantage of the multiple methods by which the delay time of intracellular gelation can be increased.

Initiation activity of EMC virus RNA, binding to initiation factor eIF-4B and shut-off of host cell protein synthesis

PICORNAVIRUSES infecting susceptible animal cells inhibit synthesis of host proteins and direct the cells to synthesise viral proteins¹. The mechanism for the shut-off of host cell protein synthesis is not understood, although several experiments indicate that initiation of host protein synthesis is specifically inhibited¹. When initiation of protein synthesis is reduced by exposing cells infected by picornaviruses to hypertonic medium, synthesis of viral proteins is greatly favoured over that of host proteins^{2,3}. This suggests that viral templates are more successful in initiation than host templates³. Competition between picornavirus RNA and host mRNAs has been shown directly by *in vitro* translation experiments^{4,5}. When these RNAs are added together in saturating amounts to a cell-free protein-synthesising system, viral RNA is preferentially translated over host mRNA^{4,5}. This competition can be relieved by addition of initiation factor eIF-4B (previously designated IF-M₃)⁶. This has suggested that eIF-4B may be present in limiting amounts in the translation assays, and that viral and host templates compete for available factor⁶. This observation is somewhat surprising, as the 5'-terminal cap sequence m⁷G^{5'}pppXmp... is involved in the binding of mRNA to eIF-4B, and picornavirus RNA is not capped (see refs 7 and 8). It has been found that other nucleotide sequences outside the cap participate in this reaction⁹, but the presence of 5'-terminal m⁷G in mRNA promotes interaction

bn

with eIF-4B and the initiation process^{7,8}. Therefore, templates with a 'capped' 5'-terminal nucleotide bind to ribosomes more rapidly than their unmethylated counterparts^{10,11}. We have shown previously that eIF-4B interacts with the RNA of encephalomyocarditis (EMC) virus, a picornavirus, in a nitrocellulose filter binding assay⁷. It has also been shown that eIF-4B is required for *in vitro* translation of EMC virus RNA¹². In the present report we have examined the basis for the competition between EMC virus RNA and a cellular mRNA at the molecular level. EMC virus RNA binds to ribosomes at a rate similar to that of capped mRNAs, suggesting that features other than the 5'-terminal m⁷G are responsible for the binding of this viral RNA. By measuring the relative affinity of globin mRNA and EMC virus RNA for eIF-4B, we have found that the viral RNA has a greater affinity for this initiation factor than globin mRNA. This high affinity for eIF-4B could explain the fast rate of initiation of the viral RNA and the shut-off of host cell protein synthesis after picornavirus infection.

The rate of binding of EMC virus RNA to ribosomes was examined in cell-free systems prepared from HeLa cells and reticulocyte lysate¹³. Labelled EMC virus RNA obtained from virions or from infected cells formed initiation complexes by binding to ribosomal subunits (Fig. 1). As was previously described^{7,10}, the cell extracts were incubated for 2 min with the inhibitor of elongation sparsomycin before addition of viral RNA. In the presence of sparsomycin, ribosomes were stuck to the initiation site of cellular mRNA. Therefore, the cellular mRNA was effectively blocked from reinitiating. This procedure avoided competition between the trace amount of the highly radioactive viral RNA added and the larger amounts of cellular mRNA present in the extracts, and enabled us to measure the kinetics of binding of viral RNA to ribosomes without interference from competitor mRNA species (Fig. 2).

Fig. 1 Binding of EMC RNA to HeLa cell ribosomes (●, c.p.m. $\times 10^{-3}$). Labelled EMC virus was obtained from infected HeLa cells incubated with ³H-uridine, and the viral RNA purified as described previously⁷. Cytoplasmic extracts were prepared from HeLa cells as described previously¹³. Each incubation contained in a final volume of 0.1 ml: 70 μ l cell extract, 5 μ l 2 mM sparsomycin, 1 μ g reticulocyte ribosomal RNA, 20 μ l of the energy mix for protein synthesis described previously¹², amino acids at 0.05 mM, K OAc at 0.12 M and Mg(OAc)₂ at 2.5 mM final concentrations. After 2 min incubation at 30 °C, 5 μ l EMC ³H-RNA (20,000 c.p.m.) were added for the time indicated. The incubations were terminated by adding 4 volumes ice-cold 0.5 M NaCl, 30 mM Mg OAc₂ and 20 mM HEPES-KOH, pH 7.4, and applied to 15–30% sucrose gradients in the same buffer. After 17 h centrifugation at 23,000 r.p.m., the gradients were fractionated through a recording spectrophotometer. An identical A₂₆₀ profile (solid line) was obtained for all gradients and is reported in the first panel only. The gradient fractions were counted after addition of 9 ml Scintiverse (Fisher). In the left panel, the incubation has been terminated immediately after addition of the RNA and the EMC RNA is not bound to ribosomes. In the other panels, the binding of EMC RNA to ribosomes is shown by the appearance of a peak sedimenting faster than the unbound EMC RNA. To determine the amount of bound EMC RNA as a per cent of input RNA (Fig. 2), the areas of the peaks corresponding to free and bound EMC RNA were measured with a Du Pont 310 Curve Resolver.

Fig. 2 Rate of binding to ribosomes of EMC RNA and of other viral mRNAs, in HeLa cell extract (a) and in a reticulocyte lysate (b). EMC ³H RNA was obtained from virions (●) as described previously⁷, or from infected HeLa cells (■) according to Fernandez-Munoz and Lavi²⁸, as follows: the cells were infected at room temperature as outlined previously⁷; after 30 min, actinomycin D was added to a final concentration of 5 μ g ml⁻¹. After 90 min, 5 μ Ci ml⁻¹ ³H uridine were added and the incubation continued for 2 h. The cells were collected, washed and homogenised as described previously¹³. The cell extract was made 0.5% in NP-40 and 30 μ g ml⁻¹ in dextran sulphate, centrifuged for 5 min to remove the nuclei, and adjusted to a final concentration of 20 mM EDTA and 1% sodium dodecylsulphate. The 35S EMC RNA was purified by three successive centrifugations on 15–30% sucrose gradients as described previously⁷. The EMC RNA had a specific activity of about 200,000 c.p.m. per μ g RNA. Other viral mRNAs were prepared as described previously for vesicular stomatitis virus polysomal mRNA⁷ (▲), and for methylated (×) and unmethylated (♦) vaccinia mRNA¹¹. The rate of binding of the different RNAs was measured as described in Fig. 1. The input of VSV mRNA was 10,000 c.p.m. per incubation. The binding assays with vaccinia mRNA have previously been described.¹¹

To resolve EMC virus RNA bound to ribosomes from unbound viral RNA, reaction mixtures were centrifuged through sucrose gradients containing 0.5 M NaCl (Fig. 1). In these conditions, single ribosomes were dissociated, whereas initiation complexes were stable¹⁰. Moreover, nonspecific association of cytoplasmic proteins with EMC virus RNA was reduced, allowing a better separation of the RNA bound to ribosomes from unbound RNA¹⁴.

In a reaction kept at 0 °C most of the EMC virus RNA not bound to ribosomes sedimented at about 70S (Fig. 1). After 1 min incubation, a peak sedimenting at about 105S was seen, and after 2 min incubation this peak was approximately equal in height to the peak of unbound EMC virus mRNA. As these peaks were incompletely resolved, it was necessary to use a Du Pont curve resolver to calculate the percentage of input RNA bound to ribosomes (see Fig. 1). This difficulty in determining the percentage of RNA bound to ribosomes was only encountered with the large picornavirus RNA. Binding of one ribosome to this RNA did not increase its sedimentation sufficiently to allow complete separation between bound and unbound RNA, as is the case with smaller mRNAs^{7,11}.

The rate of binding of EMC virus RNA to ribosomes was similar to that of capped viral mRNAs obtained from cells infected with vesicular stomatitis virus (VSV) or transcribed *in vitro* from vaccinia virions^{7,11}. The rate of binding was linear for 1 min and decreased thereafter; very little additional binding was observed after 2 min of incubation (not shown). Unmethylated vaccinia mRNA bound to reticulocyte ribosomes very slowly (Fig. 2b), as previously reported¹¹. This result was also obtained in the HeLa cell-free system (not shown). The rate of binding of cellular histone mRNA was determined in separate experiments (L. A. Weber and C. B., unpublished observation) and was found to be similar to that of the viral mRNAs. Histone mRNA is also capped¹⁵.

These results indicate that the uncapped EMC virus RNA interacts with initiation factors and ribosomal subunits to form initiation complexes at a rate comparable to that of capped cellular and viral mRNAs. As the interaction of mRNAs with initiation factor eIF-4B may play an important part in determining the rate of initiation, we measured the binding of viral RNA and globin mRNA to purified eIF-4B. The relative affinity of an RNA for this factor was determined by competition-binding experiments (Table 1)⁷. Competition-binding is the most sensitive and accurate method for comparing the relative affinity of two mRNAs for a given initiation factor, and in the conditions used only high affinity interactions were measured. This was obtained by reacting eIF-4B with labelled mRNA at low concentrations, such that only 25–30% of the input mRNA was bound (Table 1). Different unlabelled mRNAs were then added to determine their relative effect as competitors in the binding with eIF-4B. The validity of this assay was shown by experiments with globin mRNA (Table 1). The same preparation of globin mRNA purified by oligo(dT)-cellulose chromatography and gradient centrifugation⁷ was either labelled with ¹²⁵I or used unlabelled as a competitor. A 60% binding competition was observed after addition of a 2.9-fold excess of unlabelled mRNA. The increased concentration of mRNA in this reaction favoured its association with eIF-4B compared with the reaction containing unlabelled mRNA only, and consequently the apparent competition was less than the theoretical level expected. However, the important point shown by the experiments of Table 1 is that on a molar basis EMC virus RNA competed with labelled VSV and globin mRNA about 10-fold and 100-fold more effectively than unlabelled globin mRNA. Even on a microgram basis, EMC virus RNA was more effective than globin mRNA in competing with labelled globin mRNA, as 0.06 µg EMC-RNA competed almost as effectively as 0.42 µg unlabelled globin mRNA.

These findings provide direct evidence that eIF-4B was not bound randomly to RNA, in proportion to the total mass of nucleotides, but that the binding was occurring at specific site(s). Additional evidence for this specific interaction was obtained by using ribosomal RNA instead of mRNA as a competitor in the binding reactions and by directly determining the affinity of EMC virus RNA and globin mRNA for eIF-4B. Ribosomal

Table 1 EMC virus RNA competition for binding of VSV mRNA and globin mRNA to purified reticulocyte initiation factor eIF-4B (IF-M₃)

Competitor RNA	µg	pmol	mRNA bound (c.p.m.)		% Competition
			³ H-VSV mRNA	¹²⁵ I globin mRNA	
None	—	—	3713	—	—
Globin mRNA	0.25	1.1	2593	—	30
EMC RNA	0.94	0.3	1612	—	57
None	—	—	—	4702	—
Globin mRNA	0.42	1.8	—	1874	60
EMC RNA	0.06	0.02	—	2241	52

Incubations were carried out at 23 °C for 5 min in a 50 µl reaction mixture and contained 20 mM Tris-HCl, pH 7.4, 0.1 M KCl, 1 mM dithiothreitol, 1.6 µg eIF-4B plus 14,620 c.p.m. ³H-VSV mRNA (3.6 pmol) or 0.2 µg eIF-4B plus 14,700 c.p.m. of ¹²⁵I-globin mRNA (62 pmol), and amounts of competing unlabelled globin mRNA or EMC RNA as indicated. Reactions were stopped by dilution to 3 ml cold buffer (20 mM Tris-HCl, pH 7.4, and 100 mM KCl), and protein complex formation measured by collection of the radioactivity on a nitrocellulose filter as previously reported⁷. Blanks for ³H-VSV or 736 c.p.m. for ¹²⁵I-globin mRNA, representing background radioactivity, were subtracted from each value. Globin mRNA was iodinated according to a modification²⁶ of the procedure of Melnick²⁷. A molecular weight of 2.3 × 10⁵ has been estimated for EMC RNA³⁰.

Fig. 3 Binding affinity of EMC RNA (a) and globin mRNA (b) for initiation factor eIF-4B. The binding assays were carried out as described in Table 1, with 0.05 µg eIF-4B per assay and either EMC ¹²⁵I RNA (specific activity 4 × 10⁶ c.p.m. µg⁻¹) or globin ¹²⁵I mRNA (specific activity 1.8 × 10⁶ c.p.m. µg⁻¹). The reciprocals of the bound RNA (1/B) compared with the input RNA (1/S) are shown. Concentrations are in pmol. The dissociation constant (K_D) is given by the intercept of the lines with the abscissa²⁹. The K_D for EMC RNA is 1.43 × 10⁻¹⁰ mol l⁻¹ and that for globin mRNA is 1.08 × 10⁻⁹ mol l⁻¹.

RNA was found to be a poor competitor of the binding of mRNA to eIF-4B as only 100-fold greater amounts of rRNA competed appreciably in the reaction (data not shown). The affinity of EMC virus mRNA and globin mRNA for eIF-4B was determined by reacting a constant amount of initiation factor with decreasing amounts of RNA. The results are shown as a double-reciprocal plot in Fig. 3. The experimental points, and in particular those presumably measuring high affinity interactions at high RNA dilutions, fall on a line. This enabled us to measure the dissociation constants of complex formation by a graphic method (see legend to Fig. 3) and to establish that the affinity of EMC virus RNA for eIF-4B is approximately one order of magnitude higher than that of globin mRNA.

The present study is the first report of a determination of binding constants (K_D) for mRNA/eIF-4B interaction. Note that these K_D values are averages and that no assumption has been made in their calculation regarding specific sequences involved, number of binding sites, or configurational properties of the RNA or protein.

However, the significance of the binding of mRNA to eIF-4B cannot be functionally evaluated as with the presently available assays it is not possible to demonstrate that these complexes are biologically active.

The high affinity of EMC virus RNA for eIF-4B is a property of the viral RNA, which most likely determines its rate of initiation *in vitro* and its ability to compete more successfully than capped mRNAs *in vivo*. An increased rate of initiation has been shown after enzymatic addition of an m⁷G⁵p cap to the uncapped RNA of satellite tobacco necrosis virus RNA¹⁶. Addition of a cap also increases the affinity of this viral RNA for eIF-4B⁹. Picornavirus RNA competes more successfully than not only host mRNA but also other capped viral RNAs, such as VSV mRNA. In cells infected with VSV and superinfected with poliovirus, host and VSV mRNAs are translated poorly compared with poliovirus RNA^{17,18}. In these conditions, synthesis of VSV mRNA continues, but this RNA does not associate with polysomes¹⁸. Although other interpretations are possible, these observations could be explained by the high affinity of picornavirus RNA for eIF-4B reported here. The

structural basis for this high affinity is not known. Picornavirus RNA has a rather unique structure with a protein covalently bound to the 5'-terminal nucleotide^{19,20}. However, it seems unlikely that this protein plays a part in the interaction with eIF-4B and in the competition between picornavirus and host mRNA, as the viral mRNA synthesised in infected cells does not have a protein bound to the 5'-terminal nucleotide²¹⁻²³. Nucleotide sequences shared by virion RNA and by viral mRNA are presumably involved in the interaction with eIF-4B.

Initiation factors are found bound to 40S ribosomal subunits²⁴, are released after formation of initiation complexes and recycle in order to function catalytically in initiation¹³. The high affinity of picornavirus RNA for eIF-4B may interfere with the recycling of this factor. The viral RNA may form a more stable complex with eIF-4B and this may prevent the factor from functioning with host mRNAs. Golini *et al.*⁶ have proposed a similar explanation for their observation that addition of eIF-4B relieves the competition between EMC virus RNA and host mRNA for *in vitro* translation. The present study is consistent with this interpretation in that EMC virus RNA has a significantly higher binding affinity for eIF-4B than globin mRNA, a natural substrate for this initiation factor. However, binding of other initiation factors to EMC virus RNA has been reported⁷, and interaction with these other factors also plays an important part in the translation of this viral RNA²⁵. Therefore, it remains to be established whether the high affinity of picornavirus RNA for eIF-4B by itself accounts for the shut-off of host protein synthesis in virus-infected cells.

We thank Dr W. C. Merrick for purified initiation factor eIF-4B. This work was supported by NIH grants to C.B. and D.A.S., the Irma T. Hirsh Charitable Trust of New York and also NIH Research Career Development Award to D.A.S.

Does ultraviolet light enhance postreplication repair in mammalian cells?

D'AMBROSIO AND SETLOW reported an apparent enhancement of postreplication repair in Chinese hamster V79 cells¹. A first exposure of cells to ultraviolet (UV) light was said to make it possible, after re-exposure to UV, for the cells to join the DNA together to form high molecular weight DNA more rapidly than if the cells had not been previously exposed. They irradiated cells with 2.5 J m⁻² of UV 2 h before a second exposure to 5.0 J m⁻², and then pulse-labelled the cells with ³H-thymidine before chasing for 1 h. When analysed by alkaline sucrose gradient velocity sedimentation, the DNA of these cells showed a profile of radioactivity very different from that of cells irradiated only once with 5.0 J m⁻² before pulse-labelling and chasing. For cells irradiated twice the peak of labelled DNA was at a position corresponding to a higher molecular weight than the peak for cells irradiated once. I report here results confirming the data of D'Ambrosio and Setlow, but use of an alternative method of data presentation suggests that interpretations other than the one assumed by D'Ambrosio and Setlow are equally possible or maybe more likely.

When Chinese hamster cells were irradiated with 2.5 J m⁻² and, 2 h later, with 5.0 J m⁻² of UV light and then pulse-chased, their ³H-labelled DNA showed two peaks of radioactivity on alkaline sucrose gradient profiles plotted as percentage of total counts in each gradient (Fig. 1). One peak (fraction 18) was near the peak exhibited by the DNA of unirradiated cells receiving the same protocol, and the other was at a position of lower molecular weight (fraction 13). Cells treated with 7.5 J m⁻² and then pulse-chased showed a major ³H-labelled DNA peak corresponding to a low molecular weight (fraction 8) and a broad shoulder extending into the position of the peak for cells irradiated with 2.5+5.0 J m⁻². The ³H-labelled DNA from cells treated with 5.0 J m⁻² peaked at the same fraction as the minor peak of cells irradiated with 2.5+5.0 J m⁻² (fraction 13); a prominent shoulder at high molecular weight (fractions 15-18) was also present. The ³H-labelled DNA from cells treated only with 2.5 J m⁻² exhibited an alkaline gradient profile which was intermediate between that of DNA from controls and DNA from cells treated with 2.5+5.0 J m⁻² (Fig. 1). These results confirm the data of D'Ambrosio and Setlow.

D'Ambrosio and Setlow based their interpretation of the data on profiles plotted as percentage of total radioactivity in each gradient. When the same data are presented in a different form another interpretation is possible. Profiles plotted as total radioactivity per fixed number of cells (Fig. 2) demonstrate the inhibition of DNA synthesis caused by each treatment; this information is lacking in graphs plotted as percentage of total radioactivity in each gradient (Fig. 1). Figure 2 shows that the total radioactivity in fractions 18-21 from ³H-labelled DNA of cells irradiated with 2.5+5.0 J m⁻² was only slightly higher than the radioactivity in the same fractions from the DNA of cells treated only with 7.5 J m⁻², and lower than that in cells treated only with 5.0 J m⁻². The profile from cells that received only 2.5 J m⁻² shows the greatest amount of radioactivity in these fractions (except for control) but is still severely depressed from the control. When, as in Fig. 2, the data are plotted to show the large inhibitions of DNA synthesis that occur after UV irradiation, the significance of peaks that appear distinctive in Fig. 1 becomes questionable.

The data presentation in Fig. 2 also poses the question, whether the status of DNA replication in cells 2 h after 2.5 J m⁻² of UV is the same as in unirradiated cells? To answer this question, a similar experimental protocol was used but without a chase after the ³H-thymidine pulse. When the ³H-labelled DNA from these pulse-labelled cells was analysed on alkaline sucrose gradients (Fig. 3) their principal peaks were, as expected, at lower molecular weights than unirradiated cells. The ³H-

labelled DNA from cells exposed to $2.5 + 5.0 \text{ J m}^{-2}$ had a minor but significant peak corresponding to a molecular weight even higher than that of the main peak of control ^3H -labelled DNA. A very prominent minor peak at about the same point was also evident in the profile of ^3H -labelled DNA from cells exposed only to 2.5 J m^{-2} at 2.5 h before the pulse with ^3H -thymidine. The appearance of these peaks at high molecular weight is reproducible.

Analysis of profiles of both pulse-labelled and pulse-chased DNA leads to the following conclusions:

(1) Cells exposed to 2.5 J m^{-2} have not recovered from the damage in their DNA by 2.5 h after irradiation; the overall rate

Fig. 1 Alkaline sucrose gradient profiles of ^3H -labelled nascent DNA from Chinese hamster cells. Chinese hamster V79 cells, maintained in this laboratory for several years, were grown in Falcon plastic Petri dishes in Eagle's minimum essential medium (MEM) containing 15% fetal calf serum (Gibco). Exponentially growing cells incubated overnight in $0.01 \mu\text{Ci ml}^{-1}$ of ^{14}C -thymidine (57 Ci mol^{-1} ; Schwarz/Mann) were washed twice with Puck's phosphate-buffered saline G^2 and exposed to various fluences of UV light from a mercury germicidal lamp with an incident intensity of $1.3 \text{ J m}^{-2} \text{ s}^{-1}$. After irradiation, MEM was placed back on the cultures for 30 min, after which it was replaced with MEM containing $20 \mu\text{Ci ml}^{-1}$ of ^3H -thymidine ($4 \times 10^{-7} \text{ M}$). After 10 min of incubation, the radioactive medium was removed. Fresh MEM containing 10^{-4} M thymidine and 10^{-5} M deoxycytidine was added to the cells, which were incubated (chased) for 1 h before the reaction was stopped with ice-cold 0.15 M sodium chloride, 0.015 M sodium citrate (SSC). The cells were washed once with SSC, scraped into it, and a sample containing about 10^5 cells (in less than 0.5 ml) was irradiated with $1,000 \text{ rad}$ of X rays to enhance lysis³ and then added directly to 0.5 ml of lysis solution (0.5 M NaOH, 0.02 M EDTA, 0.1% NP40 [non-ionic detergent, Shell]) on top of 30 ml of preformed 5–20% alkaline sucrose gradients (0.1 M NaOH, 0.9 M NaCl, 0.01 M EDTA). Lysis proceeded in the dark at 25°C for 30 min and the gradients were then centrifuged in an SW27 rotor (Beckman) at $27,000 \text{ r.p.m.}$ for 3 h or at $12,000 \text{ r.p.m.}$ for 15 h. This gradient system has been calibrated with phage λ DNA and phage T_4 DNA as described⁴. About 25 equal-weight fractions were collected, $100 \mu\text{g}$ of calf thymus DNA were added to each fraction, and all of the DNA was precipitated with ice-cold 6 M HCl plus 6% sodium pyrophosphate. Each fraction was then filtered through GF/C filters (Whatman) presoaked with 4% HClO_4 . The filters were washed sequentially with ice-cold 4% HClO_4 , 70% alcohol, and 100% alcohol and dried; the ^{14}C and ^3H on each filter were determined with a Packard liquid scintillation spectrometer. $\circ$, Unirradiated cells; $\times$, cells irradiated only with 2.5 J m^{-2} at 2.5 h before pulse-labelling; Δ , cells irradiated with 2.5 J m^{-2} at 2.5 h before pulse-labelling and with 5.0 J m^{-2} 0.5 h before pulse-labelling; $\bullet$, cells irradiated only with 5.0 J m^{-2} at 0.5 h before pulse-labelling; $\square$, cells irradiated only with 7.5 J m^{-2} at 0.5 h before pulse-labelling. Sedimentation is from left to right. Note that the ordinate is percentage of total counts in each gradient. The majority of the ^{14}C -labelled parental DNA sedimented to the bottom of the gradient in all cases.

of DNA synthesis is still depressed by 25–50%. More importantly, the status of nascent DNA molecules in these cells is not the same as in controls; although the molecular weight of most nascent DNA molecules in treated cells is lower than in control cells, a significant number of them have a higher molecular weight (fractions 12–14, Fig. 3).

(2) When cells are exposed to 2.5 J m^{-2} of UV and then 2 h later to 5.0 J m^{-2} , 30 min after the second exposure (at the time of pulse-labelling), their nascent DNA molecules more closely resemble the nascent DNA in cells treated only with 5.0 J m^{-2} than in cells treated only with 7.5 J m^{-2} (Fig. 3). The gradient profile of DNA from cells treated with $2.5 + 5.0 \text{ J m}^{-2}$ also resembles that of DNA from cells treated only with 2.5 J m^{-2} , in that a significant amount of nascent DNA has a much higher than average molecular weight after both treatments (peak at fraction 14, Fig. 3). These results imply that 2 h after cells have been exposed to 2.5 J m^{-2} UV, many elongating DNA chains are still temporarily blocked but others have circumvented the lesions and extended to form molecules that are larger than average but still not of parental size. When the cells are subsequently exposed to 5.0 J m^{-2} , these intermediate-sized nascent DNA molecules remain as a source for further chain elongation.

(3) When pulse-chase experiments are performed, the peaks at high molecular weight (fraction 18, Figs 1 and 2) in gradient profiles of DNA from cells treated with 2.5 and 5.0 J m^{-2} probably represent (i) DNA molecules formed by the elongation of the intermediate molecular weight molecules (peak at fraction 14, Fig. 3) observed in pulse-labelled cells and (ii) DNA molecules formed by elongation of low molecular weight molecules (fraction 5, Fig. 3), as in cells exposed to 5.0 J m^{-2} alone. Elongation of intermediate molecular weight molecules accounts for the greater amounts of radioactivity at high molecular weight (fractions 18–21, Figs 1 and 2) in the DNA of cells treated with $2.5 + 5.0 \text{ J m}^{-2}$ over the radioactivity in the same fractions in cells exposed only to 7.5 J m^{-2} .

Thus, the effects of 5.0 J m^{-2} of UV light on DNA synthesis and on maturation of nascent Chinese hamster V79 DNA are different in cells that were irradiated 2 h earlier with 2.5 J m^{-2} than in previously unirradiated cells, but these differences can be explained entirely by the damaging effects of the first exposure, which cause an abnormal distribution of sizes of nascent DNA molecules at the time of irradiation with 5.0 J m^{-2} . These considerations make it unnecessary to invoke the existence of an

Identification of the haem ligands of cytochrome b_{562} by X-ray and NMR methods

X-RAY crystallography and nuclear magnetic resonance (NMR) are the two most powerful physical techniques for studying macromolecular structure. They are often used to complement one another in the study of a particular molecule. Crystallographic results have been of tremendous help in the NMR peak assignments which are subsequently used to obtain structural information in solution^{1,2}. We report the combined use of both X-ray crystallography and NMR to identify MET-7 and HIS-106 as the two ligands of the haem iron of cytochrome b_{562} .

Cytochrome b_{562} is a cytoplasmic component of *Escherichia coli*. It contains 110 amino acids of known sequence³ and a non-covalently bound haem group⁴. The sequence is shown in Fig. 1. The molecule contains two histidines at positions 7, 35 and 61. The identity of the haem ligands was previously unknown, although spectral similarities to the b -type cytochromes and sequence homology to myoglobin suggested that they were histidine⁵.

Fig. 1 Amino acid sequence of cytochrome b_{562} (ref. 3). Haem ligands, MET-7 and HIS-106 are circled. The other histidine and two remaining methionine side chains are underlined.

We have been studying the structure of cytochrome b_{562} using X-ray methods. The triclinic crystals contain two molecules in a unit cell of dimensions: $a = 33.71 \text{ \AA}$; $b = 50.48 \text{ \AA}$; $c = 32.73 \text{ \AA}$; $\alpha = 102.76^\circ$; $\beta = 86.55^\circ$; $\gamma = 106.70^\circ$ (ref. 6). The two molecules are related by a non-crystallographic twofold axis nearly perpendicular to the b axis⁷. We have obtained a single uranyl acetate derivative containing one major binding site and four minor sites per unit cell. An electron density map has been calculated at $2.5 \text{ \AA}$ resolution based on X-ray measurements including anomalous scattering from native and derivative crystals. Details of the data collection procedure, derivative preparation, heavy atom refinement and map calculation will be published elsewhere.

The map was averaged about the non-crystallographic twofold axis and plotted on a mini-map at a scale of $1.0 \text{ cm \AA}^{-1}$. The haem group was clearly seen and portions of the polypeptide chain could be traced. However, the density merged at several points, making it difficult to trace the chain unambiguously. The map was then transferred to a Richards box at a scale of $2 \text{ cm \AA}^{-1}$ in order to build a Kendrew model into the density.

It was relatively easy to identify the ligand on one face of the haem group as HIS-106 and to fit its side chain and those of its

Fig. 2 High field region of the 270 MHz ^1H -NMR spectrum of ferrocyanide b_{562} (0.2 ml 1.5 mM in D_2O , nominal pH = 7.0, 40°C). The spectrum was obtained in a Bruker 270 MHz spectrometer. The solvent resonance was suppressed^{19,20} and 7,000 transients were accumulated in a Nicolett 1180 computer. The sample was reduced with minimal amounts of crystalline sodium dithionite under argon. Dioxan was used as internal standard but all the chemical shifts are quoted in parts per million (p.p.m.) from 2,2-dimethyl-2-silapentane-5-sulphonate.

Fig. 3 Stereo photographs showing the haem group and the two ligands with adjacent side chains. The sequence asp⁶-met⁷-gln⁸ is on the right side with gln⁸ at the bottom. The sequence lys¹⁰⁵-his¹⁰⁶-gln¹⁰⁷ is on the left with lys¹⁰⁵ at the top. *a*, Skeletal model only; *b*, skeletal model superimposed on the electron density. The MMS-X molecular graphics computer developed at Washington University was used to produce the photograph. This system was not yet available during the model building stages described in the text.

immediate neighbours into the density. On the other face of the haem group, however, it was not possible to identify the side-chain ligand, and either histidine or methionine (or indeed some other side chain) could be placed in the density.

We decided that an independent method was needed to confirm the fifth ligand and to identify the sixth ligand before the model building could proceed. NMR is a non-destructive method particularly suited for this type of study. A considerable number of cytochromes in which the iron is ligated with either one histidine and one methionine⁸ or two histidines⁹⁻¹² have been characterised using NMR. The chemical shifts of the proton NMR spectrum of a methionine residue ligated to the low spin ferrous ion of a *c* type haem give a very characteristic pattern^{13,14}. These chemical shifts have been used to identify methionine as the sixth ligand of several cytochromes^{15,16}. The electron proton resonance (EPR) spectra¹⁷ of cytochromes *c*₃ from *Desulphovibrio* sp. and the absence of such chemical shifts in the NMR spectra of the low spin ferrous form of these cytochromes¹⁰⁻¹² prove that both the fifth and the sixth iron ligands are histidines. Similarly, the NMR spectra of low spin ferrocyanochrome *b*₅, which has two histidine ligands¹⁸, do not show the typical features of a methionine residue bound to the haem iron⁹.

Figure 2 shows the high field region of the high resolution proton NMR spectrum of reduced cytochrome *b*₅₆₂. The three protons intensity singlet at -2.98 p.p.m. is unequivocally assigned to the methyl group of a methionine coordinated to the haem iron^{13,14}. The one proton intensity resonances at -1.46 p.p.m., -1.75 p.p.m., -2.48 p.p.m. and -3.22 p.p.m. are assigned to the β - and γ -methylene protons of this residue. The one proton intensity singlet at 0.11 p.p.m. is in the region expected for one of the protons of histidine residues bound to low spin haem iron^{15,16} and supports earlier evidence⁵ for the nature of the fifth ligand (HIS-106).

Once it was known that the second haem ligand was methionine, it was relatively easy to identify which of the three it was. Short sequences of polypeptide chain corresponding to each methionine and two residues on either side were built. Each was tested in the density, and one sequence containing MET-7 fit the density much better than the others. The chain was then built into the density from MET-7 toward the N-terminus and forward to about residue 25. The conformation of the chain in this region consists of about four turns of α -helix. Figure 3 shows the model of the haems MET-7 and HIS-106 and their adjacent residues superimposed on the electron density map.

The model of cytochrome *b*₅₆₂ has been completed, but there are still regions of possible ambiguity in the interpretation. The electron density map is presently being refined by the method of molecular replacement²¹. The results and complete structure will be reported elsewhere.

Cytochrome *b*₅₆₂ is the first *b*-type cytochrome shown to contain both histidine and methionine as haem ligands. In contrast to cytochrome *c* the methionine occurs before histidine in sequence. However, cytochrome *c*₃ has *c*-type haems ligated by two histidines. These unusual situations suggest that a more accurate classification of cytochromes may be necessary. The redox potential of cytochromes with two axial histidine ligands is usually lower than that of cytochromes with one histidine and one methionine axial ligand¹². The redox potential of cytochrome *b*₅ ($E'_0 = 20$ mV)²² is lower than that of cytochrome *b*₅₆₂ ($E'_0 = 110$ mV)⁴. The completion of the cytochrome *b*₅₆₂ structure should be important for a better understanding of the structural control of the redox potentials of cytochromes, and of their evolutionary relationship.

Dynamic model of globular protein conformations based on NMR studies in solution

BASIC PANCREATIC TRYPSIN INHIBITOR (BPTI) is a small globular protein of molecular weight 6,500 (refs 1-17). It consists of one polypeptide chain with 58 amino acid residues, including three disulphide bonds and four phenylalanines and four tyrosines as the only aromatics¹⁸. The crystal structure at 1.5 Å resolution has been extensively refined¹⁹. In the ¹H- and ¹³C-NMR (nuclear magnetic resonance) spectra, a large number of resolved resonance lines have been assigned to particular residues in the amino acid sequence^{6,8,10-16} and related to particular aspects of the molecular conformation¹⁻¹⁷. Hence, NMR spectral similarities and differences between BPTI and related proteins can on the basis of these earlier studies be interpreted in terms of structural features in well defined locations of the protein molecule. We report here the use of NMR observations to describe the globular BPTI conformation in terms of a dynamic ensemble of rapidly interconverting molecular structures. BPTI was a suitable compound for this study as its globular form is outstandingly stable in aqueous solution (Table 1)^{1,9,20}, leaving a large experimentally accessible range for studies of modified BPTI species with reduced stability. The chemically modified and homologous proteins used are characterised in the footnotes to Table 1.

Using the extensively refined X-ray structure¹⁹ and the well resolved NMR spectra it has been demonstrated that the average molecular conformations of BPTI in crystal form and in solution are, with the exception of localised regions on the protein surface^{8,17}, very similar^{1,2,14,16} and the structure type

seen in BPTI crystals prevailed also in aqueous solutions of all the proteins in Table 1^{13,21-23}. In this study the information on the solution conformations obtained from comparison with the crystal structure of BPTI was complemented by NMR measurements of the denaturation temperature, the amide proton exchange rates with the solvent in D₂O solution and the intramolecular mobility of the aromatic rings. The conclusions on the molecular dynamics are based largely on comparison of these features in the different structurally closely related proteins of Table 1.

The denaturation temperatures (see Table 1) were determined from the transition of the ¹H-NMR spectrum of the globular proteins to a random coil spectrum^{1,27}. An additional important observation was that at the denaturation temperature, the exchange between globular and denatured protein, was slow on the NMR time scale¹⁴.

The amide proton exchange rates were obtained for numerous individual protons by measurements of the decrease of the resonance intensities with time after dissolving the proteins in D₂O (ref. 27). Approximately 25 interior amide protons could readily be studied using this technique^{1,2}. Table 1 shows rate constants for the most slowly exchanging amide proton in the different proteins^{13,22,23}.

High resolution ¹H-NMR spectra provided an unambiguous criterion to determine rotational motions of the aromatic rings of phenylalanine and tyrosine about the C_β-C_γ single bond²⁷. In BPTI, three aromatic rings were found to undergo 180° flip motions about the C_β-C_γ bond²⁸ with frequencies of the order of 50-1,500 s⁻¹ at 40° and activation energies ΔG* of the order of 15 kcal mol⁻¹. One ring was immobilised over the entire accessible temperature range, with ΔG* ≈ 20 kcal mol⁻¹ at 80° and four rings were flipping too rapidly to be studied quantitatively^{3,5,9}. In Table 1 the flipping motions for two selected rings are characterised for the different proteins.

Three features of the data obtained are worthy of attention. (1) The amide proton exchange rates are outstandingly slow for globular proteins^{29,30}, with life times of the order of several years for the most slowly exchanging protons in BPTI at neutral pH and 25°C (refs 1, 2). On the other hand, local flexibility of the protein structures is implied by the rotational motions of the aromatic rings^{3,9,27,28,31}. (2) The amide proton exchange rates are correlated with the thermal stability of the globular conformation, that is, in proteins with lower denaturation tempera-

Table 1 Denaturation temperatures, amide proton exchange rates and intramolecular mobility of aromatic rings in BPTI and six related proteins

† T_D, temperature at which at pH 5.0 equal concentrations of globular and denatured protein were observed.

‡ k_{EX}, Rate constant for the most slowly exchanging amide proton at pH 4.5 and 36°C.

§ ν, Frequency at which the rings undergo 180° flips about the C_β-C_γ bond^{3,28}, ΔG*, activation energy for these rotational motions. The data for Tyr 35 were obtained at 27°, those for Phe 45 at 4°C.

|| In these proteins, the modifications are immediately adjacent to Tyr 35; as a consequence, the Tyr 35 spectrum corresponds to the situation of rapid exchange over the entire accessible temperature range.

¶ BPTI and TRAM-BPTI were compared in different conditions. In 1M guanidinium chloride solution at pH 6.0, T_D was 75° for BPTI and 68° for TRAM-BPTI. At pH 6.0 and 55°, k_{EX} was approximately eight times larger for TRAM-BPTI than for native BPTI.

ture the amide proton exchange is faster. (3) The rotational motions of the aromatic rings are not correlated with the thermal stability or the amide proton exchange, that is, for corresponding rings similar flip frequencies prevailed in the different proteins, unless the immediate ring environment was affected by the protein modification. These observations were used to characterise the globular solution conformations of the proteins studied.

Earlier investigations of amide proton exchange in globular proteins have resulted in the suggestion that the exchange occurs by admixture of 'open' structures, O(H), to the 'closed' globular form of the molecules, C(H) (refs 29, 30). Depending on the relative rates for the closing of the protein, O(H) $\rightarrow$ C(H), and the acid/base catalysed exchange of exposed amide protons in the open forms O(H), the overall proton exchange rate k_{EX} may be governed either by an EX₁ or an EX₂ mechanism^{29,30}. For BPTI, an EX₂ mechanism was indicated by the pH dependence of k_{EX} in the range 0.5–11.0. The correlation between denaturation temperature and amide proton exchange rates for the different proteins in Table 1 further implies that the equilibrium C(H) $\rightleftharpoons$ O(H) involves global variations of the protein structure. This is also supported by the observation that, with few exceptions, the order of the relative exchange rates for the individual amide protons was the same in all the proteins studied^{1,13,17,22,23}. On the other hand, the lack of a correlation between the frequencies of the 180° flips of the aromatic rings and the denaturation temperature or the amide proton exchange rates shows that the open forms O(H), which mediate the exchange of interior amide protons, cannot be in the same class as the thermally denatured proteins. This implies that the local environment of the aromatic rings in the closed form C(H) of the proteins is also essentially preserved in the open forms O(H). Independently, admixture among the open species O(H) of molecular structures corresponding to the thermally denatured protein was excluded on the grounds that the transition from denatured to globular BPTI was slow on the NMR time scale²⁷ even at the denaturation temperature T_D (ref. 14), as a slow closing rate O(H) $\rightarrow$ C(H) would not be compatible with the observed kinetics of the amide proton exchange¹³.

From the above considerations it seems that the 'globular solution conformations' of the proteins in Table 1, and probably proteins in general, are best described as dynamic ensembles of all the structural species C(H) and O(H) involved in the amide proton exchange, where the Boltzmann law favours population of species closely related to C(H) over the population of more extremely opened forms. The data suggest that previously quoted (refs 30, 32) near-equality in several cases of ΔG^0 between the closed and open protein structures involved in amide proton exchange, C(H) and O(H), and ΔG^0 between the globular conformation and the denatured protein is coincidental. In the proteins of Table 1, structural species corresponding to the thermally denatured forms are excluded by a sizeable energy barrier from the rapid conformational equilibria which govern the exchange of interior labile protons. That the hydrophobic pockets which enclose the aromatic rings in the proteins used are apparently preserved in the open structures O(H) is compatible with the assumption that the molecular fluctuations promoting the amide proton exchange consist primarily of intramolecular translational and rotational motions of intact hydrophobic domains relative to each other. Such fluctuations would primarily open the hydrogen bonded secondary structures which link the different hydrophobic pockets¹⁹. Independently, the mobility of the aromatic rings would be correlated with the internal structural flexibility of the individual hydrophobic domains. Hydrophobic stability domains as evidenced here in one class of globular proteins might quite generally play an essential role in the architecture of protein molecules, a role which may so far have been assigned too one-sidedly to the regular secondary structures adopted by the polypeptide backbone³³. In particular, the lack of correlation of the preservation of the hydrophobic pockets surrounding the aromatic rings with the overall stability of the globular protein conformation

indicates that such hydrophobic domains might be formed at an early stage of polypeptide folding, possibly even as primary nucleation sites for the folding process.

The observed correlation between amide proton exchange rates and denaturation temperature (Table 1) may in this model be rationalised by the assumption that the energy barrier ΔG^* separating the globular conformation from the denatured forms of the protein can be overcome only by cooperative structural fluctuations resulting from overlap of different open structures O(H). With the increase of the population of states O(H) when approaching the denaturation temperature, the probability of such cooperative processes is greatly enhanced. The cooperative fluctuations would also cause destabilisation of the hydrophobic domains, thus causing a sharp transition to the denatured form.

While a thorough comparison of our results with other studies of protein flexibility must be deferred to a subsequent, more detailed paper³⁶, it seems important to point out that the many-parameter characterisation of internal motions in globular proteins by high resolution NMR provides a considerably more detailed description of interior parts of the molecules than that implied, for example, by the terms 'fluid-like' or 'continuous visco-elastic'³⁵ suggested in interpretations of theoretical model studies.

Two contiguous conformations in a nucleic acid duplex

DNA CONFORMATIONS and properties depend on DNA sequence and on environmental conditions¹⁻³. It has been suggested that specific regulatory sites on DNA might have unique secondary conformations². Conformational transitions, and the propagation of these transitions along a DNA helix, have been proposed as mechanistic steps in RNA transcription⁴ and DNA replication^{3,5} as well as having possible regulatory roles in these functions⁶. Whether two significantly different conformations can coexist in a DNA duplex, however, has been uncertain. The *A* and *B* structural forms of DNA differ greatly in base-pair tilt, base-pair positioning and sugar ring pucker^{7,8}. Most DNA duplexes are generally considered to adopt the *B* form in solution whereas RNA duplexes and DNA · RNA hybrids have only been found to adopt *A* forms⁹⁻¹¹. We have synthesised a polynucleotide complex (Fig. 1) which has covalently linked DNA · DNA duplex and RNA · DNA hybrid tracts. NMR studies on this molecule demonstrate that the *A* and *B* conformations can coexist along a nucleic acid duplex and also that significant propagation of conformational transitions along DNA helices is unlikely.

Fig. 1 A schematic diagram illustrating the coexistence of two different helical conformations in the $dG_n \cdot rC_{11}dC_{16}$ duplex.

Synthesis of the block complex, $dG_n \cdot rC_{11}dC_{16}$, was achieved as follows. rC_n and dC_n were hydrolysed to oligonucleotides by partial alkaline¹² and pancreatic DNase¹³ digestion, respectively. rC_{11} and dC_{16} oligomers were isolated from the digests using reversed-phase ion-exchange chromatography (RPC-5) (ref. 14). Alkaline phosphatase treatment removed the 3'-terminal phosphate from rC_{11} ; dC_{16} was acetylated at the terminal 3'-OH position using acetic anhydride¹⁵. rC_{11} and $dC_{16}OAc$ were mixed with dI_n and T4 DNA ligase was used to covalently link the RNA and DNA oligomers¹⁶. The product oligonucleotide, $rC_{11}dC_{16}OAc$, was isolated from both the dI_n template and the unreacted rC_{11} and $dC_{16}OAc$ substrates by RPC-5 chromatography at 65 °C. Finally, $rC_{11}dC_{16}OAc$ and dG_n ($S_{20,w} \approx 3$) were annealed to form Watson-Crick duplexes according to a previously published procedure¹⁷, which also removed the acetyl group from the 3'-OH terminus of the block oligonucleotide. Four milligrams of $dG_n \cdot rC_{11}dC_{16}$ were prepared for high resolution proton magnetic resonance studies. Physical, spectroscopic and biochemical determinations similar to those reported previously^{2,12-14} were used to characterise this nucleic acid (E.S. and R.D.W., in preparation).

In Fig. 2 the resonances in the proton NMR spectrum of $dG_n \cdot rC_{11}dC_{16}$ are compared to control $dG_n \cdot rC_{22}$ and $dG_n \cdot dC_{22}$ spectra. For $dG_n \cdot rC_{22}$, the resonance from the hydrogen-bonded G-N₁ proton is at 12.7 p.p.m. and the G-H₈ and C-H₆ protons resonate at 7.2 and 7.8 p.p.m. respectively. The positions of all these resonances are similar to the analogous resonances for $rG_n \cdot rC_n$ (see Fig. 2 legend). X-ray diffraction studies on $rG_n \cdot rC_n$ and $dG_n \cdot rC_n$ (E.S., R.D.W., A.G.W. Leslie and S. Arnott, unpublished) in polynucleotide fibres indicate that these duplexes adopt only *A* conformations.

For $dG_n \cdot dC_{22}$, on the other hand, the G-N₁ proton resonance is at 12.98 p.p.m. and both G-H₈ and C-H₆ protons resonate at 7.55 p.p.m. X-ray fibre diffraction indicates that $dG_n \cdot dC_n$ can adopt either *A* or *B* conformations¹⁸. In the conditions of high relative humidity usually extrapolated to solution studies, the *B* conformation is observed. The NMR spectrum of $dG_n \cdot dC_{22}$ supports this extrapolation since the

Fig. 2 A comparison of the 300 MHz NMR spectrum of $dG_n \cdot rC_{11}dC_{16}$ with the spectra of appropriate control samples. The assignments of the various resonances are indicated. Spectra were obtained using a Varian HR-300 spectrometer operated in the field sweep mode. The spectra shown were measured at 35 °C except for $dG_n \cdot rC_{22}$ which was measured at 22 °C. The low field spectra (12–14 p.p.m.) for $dG_n \cdot rC_{22}$ and for $dG_n \cdot rC_{11}dC_{16}$ are at twice the gain of the spectra for the aromatic regions (6–9 p.p.m.). For $dG_n \cdot dC_{22}$, the low field spectrum is at four times the gain of the aromatic region. NMR samples were prepared by dialysing against a dilute buffer solution and then concentrating the sample 20-fold by rotary evaporation. The final buffer concentration was about 50 mM phosphate, 0.5 mM EDTA, pH 7.0. 2–3 mg of nucleic acid was present in the final volume of 0.12 ml. For $rG_n \cdot rC_n$ at room temperature, the resonance from the hydrogen-bonded G-N₁ proton is at 12.6 p.p.m. whereas the G-H₈ and C-H₆ protons resonate at 7.27 and 7.95 p.p.m., respectively (D. Lerner, unpublished).

observed resonance positions for this complex are consistent with those calculated using ring current shift theory for stacked G · C base pairs in the *B*-DNA conformation^{19,20}. The assignment of *A* and *B* conformations in solution for $dG_n \cdot rC_{22}$ and $dG_n \cdot dC_{22}$, respectively, is in accordance with other NMR studies on oligonucleotides which show that ribonucleic acids prefer *A* forms²¹⁻²³ whereas deoxyribonucleic acids prefer *B* forms²⁴⁻²⁶.

The proton NMR spectrum of $dG_n \cdot rC_{11}dC_{16}$ shown in Fig. 2 is clearly a composite of the $dG_n \cdot rC_{22}$ and $dG_n \cdot dC_{22}$ spectra. The ratios of the resonance intensities at the various positions are consistent with the 11 : 16 hybrid to DNA duplex ratio of the complex. The obvious conclusion from this spectrum is that the two ends of the block complex adopt two different conformations. Apparently, the significant differences between the *A* conformation of the RNA · DNA hybrid end of the molecule and the *B* conformation of the DNA · DNA end can be accommodated so that the two structures coexist within a single short oligonucleotide duplex.

We recognise that the NMR spectrum presented in Fig. 2 for $dG_n \cdot rC_{11}dC_{16}$ could be interpreted as an equilibrium mixture of duplexes totally in one conformation or the other, rather than two conformations (*A* and *B*) present in a single duplex. This is unlikely since: (1) RNA · DNA hybrids have never been found to adopt *B* conformations; (2) judging from the line widths, the rate of conversion between the two conformations in equilibrium would have to be extremely slow (less than 30 s⁻¹); (3) the equilibrium constant of the system would have to be accidentally very close to 11/16 and (4) when actinomycin D, which binds to DNA duplexes but not to DNA · RNA hybrids²⁷ was added to the block polymer sample, resonances from 12.98 p.p.m. (*B* form) were selectively shifted upfield to 11.9 p.p.m. with no

effect on the intensity in the 12.7 p.p.m. (A form) peak (data not shown). This result is difficult to explain in terms of an equilibrium model. We feel these arguments amply justify our straightforward interpretation of the spectra.

The peak positions of the spectra shown in Fig. 2 for the block polymer $dG_n \cdot rC_{11}dC_{16}$ are indistinguishable from the spectra found with 3-component helix $dG_n \cdot (rC_{18} + dC_{18})$ (data not shown). Thus, any disruption of the nucleic acid helix of $dG_n \cdot rC_{11}dC_{16}$, which is created at the junction of the A and B conformations, is minimal as measured by proton NMR.

X-ray diffraction and infrared dichroism studies have indicated that $dG_n \cdot dC_n$ helices show a greater disposition to adopt A conformations than DNAs having random base sequences^{18,28}. Nevertheless, the $dG \cdot dC$ end of $dG_n \cdot rC_{11}dC_{16}$ maintains a B conformation despite the adjacent A conformation of the RNA · DNA hybrid. This finding provides clear evidence against significant propagation of secondary conformations along DNA helices, and is consistent with earlier NMR studies on $(dC_{15}dA_{15}) \cdot (dT_{15}dG_{15})$ ²⁰ and with investigations of drug binding to DNA²⁹. Propagation of these types of structural transitions in linear DNA cannot, therefore, explain either long-range genetic regulation such as seen in the arabinose operon³⁰ or some of the steps in DNA replication^{3,5}.

The presence of two conformations in a single duplex must necessitate some perturbation of the helix at the junction of the conformations. The peaks in the NMR spectrum of $dG_n \cdot rC_{11}dC_{16}$ are not sufficiently resolved to provide detailed information concerning this point. Model building, however, shows that neighbouring A and B conformations in a nucleic acid duplex can result in a 'bend', that is, a change in the direction of the duplex helix axis, with a junction involving only one base-pair (E.S., R.D.W., C. J. Alden and S. Arnott, manuscript in preparation).

This study demonstrates that two quite different conformations can exist as neighbours on a DNA helix. Thus, sequence-specific conformational sites, possibly present at genomic regulatory regions, could exist if these sequences were approximately one turn of helix (10 base pairs) in length. Shorter conformationally unique sequences might also be allowed. Prime candidates for structurally unique sites on natural DNAs would be the dA : dT sequences found in several eukaryotes^{31,32}. $dA_n \cdot dT_n$ has only been observed in the B' conformation, a variant of the classical B-DNA structure, and never in an A form³³. This behaviour may be relevant to the postulated role of dA · dT tracts in termination of RNA transcription³⁴ since RNA · DNA hybrids are apparently limited to A conformations. Other candidates for conformationally unique sites in DNA include regulatory control regions, for example the *lac* operator has been implicated to be structurally unique³⁵. These concepts have been recently reviewed¹.

Comparison of theory to experiment for DNA thermal denaturation

THEORETICAL profiles of the thermal denaturation of random sequence DNA that were calculated by Frank-Kamenetskii and Vologodskii¹ displayed a number of narrow subtransitions. In several ways these subtransitions resembled the thermalities observed experimentally in derivative denaturation profiles^{2–7}. Lyubchenko *et al.*⁸ extended their theoretical work to include the known sequence of Φ X174 DNA and claim that not only the shape of prominent subtransitions, but also the number and denaturation temperatures are essentially the same for both calculated and observed denaturation profiles. We suggest that the agreement between current theory and experiment is not as satisfactory as has been implied, and that at least one critical parameter has been neglected in the theory and ignored in the discussions of Lyubchenko *et al.*⁸.

Thermal denaturation profiles were calculated for the double-stranded DNA of Φ X174, using the complete nucleotide sequence published by Sanger *et al.*⁹. These calculations utilised the Fixman and Frère¹⁰ modification of Poland's method¹¹, and assumed the generally acceptable values of parameters chosen by Lyubchenko *et al.*⁸ for their calculations with the same DNA sequence. As expected, our theoretical results for the whole virus DNA closely parallel those of Lyubchenko *et al.*⁸. However, we find that the theoretical denaturation profile of the *HapII*, Y1 restriction fragment of Φ X significantly departs from that published by Lyubchenko *et al.*⁸, rendering the comparison of the calculated profile to the corresponding experimental data⁴ notably less precise. We do not understand this discrepancy.

The theoretical denaturation profiles for the whole virus DNA are illustrated in Fig. 1a and b, with values of the parameters T_{AT} and T_{GC} (the average melting temperatures of the A · T and G · C base pairs within a duplex polymer), corresponding to 30 mM and 195 mM sodium ion concentrations, respectively. As noted in Fig. 1 legend, the parameters σ , α , and U are identical to those of Lyubchenko *et al.*⁸; the values for T_{AT} and T_{GC} are based on the values of Lyubchenko *et al.*⁸ (which correspond to 0.1 SSC or 19.5 mM Na^+), together with an extrapolation of $15.7^\circ C / \log [Na^+]$, which brings the midpoint of the theoretical and experimental profiles into maximum correspondence for this DNA.

Evidently, the main features of the theoretical profiles do not vary appreciably with salt concentration, except for the requisite

translation in temperature. Indeed, the small difference in shape between our theoretical profiles is largely removed if the variation of the denaturation enthalpy with salt concentration¹² is taken into account. As previously reported^{7,8}, the main features of the theoretical profiles are insensitive to moderate changes in the parameters σ and $T_{GC} - T_{AT}$, and only small changes in the profile were demonstrable when different sequence termini were used to initiate the calculation. We have also subjected this DNA sequence to a 3% random substitution of base pairs to estimate the influence of possible errors in the sequence of Sanger *et al.*⁹; no visible change in the profile resulted.

Fig. 1 *a, b*, The theoretical helix-to-coil transition profiles of duplex Φ X174 DNA. The parameters used for this calculation were $\sigma = 5 \times 10^{-5}$ (cooperativity factor), $\alpha = 3/2$ (loop entropy exponent), and $U = 8$ kcal per mol base pair (transition enthalpy). The thermal derivative of the mass fraction in coil form ($-d\theta/dT$) is plotted in (*a*) for $T_{AT} = 328.9$ K and $T_{GC} = 371.3$ K, which should correspond to 30 mM Na^+ , and in (*b*) for $T_{AT} = 341.4$ K and $T_{GC} = 383.8$ K, which should correspond to 195 mM Na^+ (SSC). *c, d*, Experimental high resolution thermal denaturation profiles of Φ X174 RF III DNA. The solution for (*c*) contains 30 mM Na^+ (29 mM Cl^- , 1 mM cacodylate, 10^{-4} M EDTA, pH 7), and that for (*d*) contains 195 mM Na^+ (150 mM Cl^- , 15 mM citrate, pH 7.2). The thermal derivative of the denatured mass fraction ($-d\theta/dT$) was calculated from the optical hyperchromicity at 270 nm using a 9-point least-squares cubic polynomial fitting routine^{2,3}. Standard deviations and fitting routine distortions are approximately the size of the illustrated points. Since the replicative form (RF-I) of Φ X174 cannot denature as a normal linear duplex because of its topological constraints, the initial DNA preparation was subjected to a single double-strand break per molecule using the endonuclease from *Pseudomonas* Bal-31 [*Altaromonas espejiana*]. The repurified RF-III molecules were then subjected to denaturation analysis. We assume that the break occurs randomly along the molecule, as is the case for supercoiled SV40 DNA (unpublished data).

For a quantitative comparison of theory and experiment we have collected high resolution thermal denaturation data on double-stranded am3 Φ X174 DNA in solutions containing 30 mM and 195 mM sodium ions (Fig. 1*c, d*, respectively). The techniques and equipment used were previously described^{2,3}. These results were obtained in conditions that closely approximate equilibrium throughout the helix-to-coil transition and should be directly comparable to the theoretical profiles of Fig. 1*a* and *b*.

Clearly, the thermalites of the two theoretical profiles bear no obvious systematic relationship to the experimental profiles. More importantly, the theory totally fails to reflect the radical changes that occur in denaturation profiles upon variation of the concentration of DNA counterion. In agreement with our previous studies², the number and mean breadth of the thermalites composing our experimental profiles appear similar although the two profiles are obviously distinctive. We must also point out that the mean breadth of the resolvable thermalites in the experimental profiles is consistent with our previous measurements² but is significantly narrower than the subtransition breadths published by Wada *et al.*⁴ for two Φ X174 restriction fragments. This difference probably arises because of our higher thermal resolution^{2,3}. A similar examination of component breadth could not be made on the data of Lyubchenko *et al.*⁸, whose experimental resolution was substantially lower. However, there is a distinct similarity between their 0.1 SSC experimental profiles and our 30 mM profile (Fig. 1*c*), and our experimental results in 0.1 SSC (not shown) are in general agreement, although our resolution clearly delineates maxima and minima where inflections appear in the data of Lyubchenko *et al.*⁸. Further, their 74–75 °C component is several times larger than the corresponding region in our results, which might reflect a bacterial DNA contamination mentioned by those authors.

It must be concluded that our understanding of the process of DNA thermal denaturation is incomplete, and it is not clear what modifications of the theory need be made. Including more sequence information as done by Wartell¹³ or distinguishing sequence doublets as proposed by Borer *et al.*¹⁴ may advance the precision of the calculation, but is not likely to provide the major theoretical revision necessary to accommodate the critical dependence of the denaturation profile upon salt concentration. Indeed, the latter observation may be taken as evidence that an electrostatic determinant differentially influences the stability of cooperative sequences, as we have previously suggested². Until the mechanism underlying this effect has been satisfactorily described, it is clear that the theory of DNA denaturation must be considered inadequate.

This study was supported by NIM grant GM-23067 and NCI grant CA-11430. We thank Dr Horace Gray (University of Houston) for RF Φ X174 DNA preparations.

matters arising

The *Q*-statistic and the diversity of floras

LAMONT ET AL.¹ accept in principal the *Q*-, or quartile, statistic for floral diversity, combining both equitability and species richness, that we proposed^{2,7} and defined as

$$Q = \frac{\frac{1}{2}S}{\log_e R_2 - \log_e R_1}$$

where *S* is the total number of species in the sample. We selected the 25% (*R*₁) and 75% (*R*₂) quantiles, the quartiles, and evaluated the characteristic slope of the cumulative species abundance curve over this range because, from our experience of insect catches³, a considerable proportion of the species may be represented by singletons. We would expect this quartile statistic to be less affected by sample size than that based on the 10% and 90% quantiles proposed by Lamont *et al.*¹. However, we are more concerned about their justification for the statistic and the results thereby obtained.

Although their characteristic slope, like the *Q*-statistic, may be equated with the reciprocal of the slope of the rank-abundance plot (Fig. 1), standard regression methods are not applicable in the way Lamont *et al.* suggest. Because successive points are very highly correlated, sampling errors will be considerably underestimated, and the method breaks down for discrete data, like those quoted for Malaysian rain forest⁴, in which a large proportion of species are represented by one or two individuals. Our own technique is to fit a stabilising model to the species frequency distribution, rather than to the rank-abundance plot, by weighted least squares⁵. The statistic may then be derived from the parameters of the model (for the log-normal $Q = 0.371 S/\sigma$ and for the log-series $Q = \alpha$) and this method will be highly efficient and applicable for both continuous and discrete data.

Lamont *et al.*'s failure to fit a model¹, in particular the log-normal, seems to discourage them. However, comparison of our Fig. 1 with theirs suggests that the fault lies, not in the models but in their fitting procedures. In spite of the floral richness of their site the abundance distribution does not seem unusual. Further, their curve-fitting tests, based on comparison of the residual sums of squares with the percentage points of a χ^2 distribution (their Table 1), are inappropriate because the size of these residuals will depend on the scaling used.

Using the more appropriate techniques now available in the MLP program⁶ we have fitted the log-normal and gamma³ models (the simpler log-series being unsuitable for continuous data¹) to the heathland data they produced. The fit of both models is good, the gamma slightly the better of the two (Table 1), and, while the two models predict different numbers for the rarest and commonest species, the *Q*-statistics for the midrange species are similar and close to the empirical value obtained by evaluating the quartiles *R*₁ and *R*₂ directly from the sample values (Table 2).

Lamont *et al.*¹ state that the diversity of their heathland sample is "as high if not higher than those for the most diverse communities previously recorded, including the richest of tropical rain-forests". But, when all the diversity indices are evaluated for the data quoted by Lamont *et al.* for Malaysian tropical rain forest^{1,4}, they are found to be consistently higher than those for Western Australian heathland by a factor of between two and three (Table 2).

Table 1 Fit of log-normal and gamma models to species frequency data from the Western-Australian heathland site

Importance value class	No. species observed	No. expected log-normal	No. expected gamma
<0.05	14	10.0	17.9
0.05–0.1	8	12.2	9.1
0.1–0.2	20	20.0	13.5
0.2–0.5	35	36.5	27.0
0.5–1.0	23	29.8	28.2
1.0–2.0	30	25.8	32.1
2.0–5.0	30	22.7	33.7
5.0–10.0	10	8.8	9.3
>10.0	2	6.2	1.1

Parameter estimates:

log-normal ($\chi^2_6 = 11.7, P > 0.05$)

$\mu = -0.53, \sigma = 1.57$

Gamma ($\chi^2_6 = 8.2, P > 0.05$)

$m = 1.51, k = 0.60$

The chi-squared goodness of fit test relies on the assumption that number of species observed in each class is a Poisson variable.

Table 2 Values of indices of diversity for Malaysian rain forest and Western Australian heathland

Index	Formula	Tropical rain forest Malaya ⁴	Heathland site Western Australia ¹	Ratio forest/heath
Simpson's (inverse)	$\frac{1}{\sum_i p_i^2}$	84.2	32.7	2.57
Shannon-Wiener (exponent)	$\exp\left(-\sum_i p_i \log p_i\right)$	149.1	69.4	2.15
<i>Q</i> -statistic	$\frac{\frac{1}{2}S}{\log(R_2/R_1)}$	104.6	38.2	2.74
	log-normal	105.9	40.6	2.61
	gamma	105.6	38.6	2.74
	log-series (α)	114.2	28.0*	
Whittaker's	$\frac{S}{4[(\sum_i (\log p_i - \log \bar{p})^2/S)]^{\frac{1}{2}}}$	77.1	28.3	2.72
log-cycle	$\frac{S}{\log p_1 - \log p_s}$	80.7	21.2 (24.4)†	3.81 (3.31)†
